## Abstract

The cladiellins (also known as eunicellins) are oxygen-bridged 2,11-cyclised cembranoids, isolated from gorgonian octocorals and soft corals. They present an unusual oxatricyclic ring system composed of a hydroisobenzofuran and an oxonene unit. The natural role of these cembranoids is proposed to involve predatation deterrence, and biologically they have been shown to exhibit in vitro cytotoxicity against various cancer cell lines, anti inflammatory properties antimicrobial activities.

The Clark group has been interested in the synthesis of cladiellins for some time, and in 2007 Clark and co-workers reported the total synthesis of vigulariol. This thesis describes the investigation of the synthesis of both $E$ - and $Z$-cladiellins using our general strategy.

The key transformations in the synthetic route are ring formation reactions. Firstly, a $\mathrm{Sml}_{2}$-mediated reductive cyclisation forms the tetrahydropyran ring, then a tandem oxonium ylide formation [2,3]-sigmatropic rearrangement constructs the oxabicyclo[6.2.1]undecenone bicyclic core. Finally, a Diels-Alder cycloaddition reaction forms the third ring of the tricyclic core of the cladiellins. Particular interest was given to the tandem oxonium ylide formation [2,3]sigmatropic rearrangement reaction. This transformation was studied in order to develop conditions allowing the selective formation of the $E$-oxonene ring needed for the synthesis of the $E$-cladiellin tricyclic core.

Herein, is presented work towards the synthesis of ophirin B, a cladiellin bearing a Z-oxonene alkene, as well as the enantioselective total synthesis of eight cladiellins obtained from an E-cladiellin tricyclic core: (-)-cladiella-6,11-dien-3ol, (-)-cladiell-11-ene-3,6,7-triol, (-)-3-acetoxycladiella-6,11-diene, 3-acetoxy-cladiellin-11-ene-6,7-diol, (-)-sclerophytin A, (-)-sclerophytin B, $(+)$-deacetylpolyanthellin A and (+)-polyanthellin A in 20 to 24 steps from our allylic alcohol precursor.

## Declaration

I declare that, except where explicit reference is made to the contribution of others, the substance of this thesis is the result of my own work and has not been submitted for any other degree at the University of Glasgow or any other institution.

A portion of the work described herein has been published elsewhere as listed below.

Enantioselective Total Syntheses of Three Cladiellins (Eunicellins): A General Approach to the Entire Family of Natural Products J. Stephen Clark, Raphaëlle Berger, Stewart T. Hayes, Lynne H. Thomas, Angus J. Morrison and Luca Gobbi Angew. Chem. Int. Ed. 2010, 49, 9867-9870.

## Acknowledgements

First, I would like to show my sincere gratitude to my supervisor, Prof. J. Stephen Clark for his help and support over the past three years. I would like to thank him for offering me the opportunity to work in his group on such an exciting and challenging project, and for having been approachable when I needed him and giving me the freedom to find my own solutions and try my own ideas.

I would like to thank my industrial supervisor Dr. Angus Morrison for his support and extensive advice about my project and my future career. I really enjoyed having someone giving me an external point of view on my different problems. Be sure that the natural products celebratory tequilas have kept me motivated!

For funding I would like to thank the University of Glasgow, WestChem and Organon/Schering-Plough/Merck. Special thanks go to everyone at Newhouse for having made my three month CASE placement so enjoyable. Despite the difficult times of the merge and then the closing period you have made me feel welcome and part of the team. I wish you all the best for the future.

I would like to thank the technical staff at the University of Glasgow for their help over the last three years and Dr Lynne Thomas, Dr Mark Schmidtmann and Dr Andy Parkin for X-ray crystallography.

An enormous thank you goes to all the past and present members of the Clark group; Carine, Delphine, Anna, Flo, Alex, Bora, Fred, Serena, Euan, Subha, Thomas, Derek, Emelie, Emilie, Flavien, Ralph, Anthony, Andy, Guang and Paloma. Thank you all for your advice, your friendship and for making the many hours spent in the lab enjoyable. I will never forget the good times spent in the lab, at the gym or of course in the pub. You guys were my substitute family over the past three years.

A special thank you goes to everyone who helped proofreading this thesis, in particular Euan and Anthony.

I have had a great time in Glasgow and made some wonderful friends. I especially enjoyed exploring the Scottish highlands with the German (Mona, Frank, Toby, Daniela, Johannes) and French (Carine, Flo, Alex, Fred, Flavien, Anthony) teams. I would also like to thank everybody who has contributed to make these years in Scotland so enjoyable and unforgettable.

Finally I would like to thank my family for their understanding and support from a distance.

## 1 Introduction

### 1.1 The 2,11-Cyclised Cembranoid Family of Natural Product

Over the last forty three-years a large number of biologically active oxygen-bridged 2,11-cyclised cembranoids have been isolated from marine invertebrates such as gorgonians and soft corals. These marine metabolites possess unique structures that are not found in natural products isolated from terrestrial sources. This family of natural products displays a large degree of structural diversity as well as varied biological and pharmacological activities such as cytotoxicity, anti-inflammatory effects, and anti-malarial properties. Oxygen-bridged diterpenes have been classified in four categories; ${ }^{1}$ the cladiellins (also known as eunicellins), the briarellins, the asbestinins, and the sarcodictyins (Scheme 1). The cladiellins, briarellins, and asbestinins are characterised by a tricyclic diterpenoid structure associated with an unusual ether bridge between C-2 and C-9 (cladiellin numbering). The briarellins and the asbestinins posses an additional seven-membered ether ring between C-3 and $\mathrm{C}-16$. The sarcodictyins, unlike the others, feature an ether bridge between $\mathrm{C}-4$ and C-7.

Scheme 1

### 1.1.1 Proposed Biosynthesis

A possible biosynthetic pathway to the ether-bridged diterpenes was first postulated by Faulkner and co-workers upon isolation of the first sarcodictyin. ${ }^{2}$ In this report, Faulkner proposed that a 2,11-cyclisation reaction (cembrane nomenclature) of the cembrane ring skeleton initiates the biosynthetic pathway that leads to all four sub-classes of compound (Scheme 1). Cyclisation of the cembrane skeleton between $\mathrm{C}-2$ and $\mathrm{C}-11$ (cembrane nomenclature) and ether ring formation between C-2 and C-9 (cladiellin nomenclature) affords the cladiellin. Additional seven-membered cyclic ether formation between C-3 and $\mathrm{C}-16$ (cladiellin nomenclature) gives the briarellins. The asbestinin skeleton is obtained from the briarellins via a 1,2 methyl shift from $\mathrm{C}-11$ to $\mathrm{C}-12$. The sarcodictyins are obtained by the same initial 2,11-cyclisation reaction of the cembrane skeleton, but with ether ring formation occurring between C-4 and C-7 (cladiellin nomenclature). Although no systematic study of the biosynthesis has been reported, the isolation of members of the different sub-classes from a common organism provided circumstantial evidence for Faulkner's proposed biosynthetic pathway.

### 1.1.2 The Cladiellin Family

The cladiellin (eunicellin) family is the most abundant class of oxygenated 2,11-cyclised cembranoids. Currently, more than 60 members of the cladiellin family have been isolated from marine source.

### 1.1.2.1 Isolation and Characterisation

The first oxygenated 2,11-cyclised cembranoid isolated was eunicellin (Figure 1). The isolation of this compound was reported in 1968 by Kennard and co-workers, from the soft coral Eunicella stricta found off the coast of Banyuls-sur-Mer in France. ${ }^{3}$ The structure of eunicellin was determined based on NMR studies and on the X -ray diffraction analysis of its dibromide 1 derivative.

Eunicellin

1

Figure 1

The structures of the majority of the cladiellins have been determined by NMR analyses alone. However, some of the cladiellins have been subjected to X-ray crystallography in order to determine their relative configuration. The first determination of the absolute configuration of a cladiellin was performed by Ochi and co-workers in 1988 for litophynin C. ${ }^{4}$ Since then, the absolute configurations of other natural products in the family have been deduced base on this assignment. Subsequent development of the modified Mosher method ${ }^{5}$ enabled the absolute configuration of many members of the family to be solved with reasonable certainty.
The cladiellins possess a large degree of functional diversity, but in all cases C-3, $\mathrm{C}-6, \mathrm{C}-7$ and $\mathrm{C}-11$ are either oxygenated or $\mathrm{sp}^{2}$ hybridised (Figure 2). The C-3 stereogenic centre was long thought to have the $R$ configuration in all the cladiellins, but Paquette and co-workers have recently re-evaluated previous assignments and have concluded that, in some cases, the other configuration is found at C-3. ${ }^{6}$ Functionalisation at positions C-4, C-8, C-12, C-13, C-15, C19 and C-20 (marked with a *, Figure 2) varies significantly across the cladiellin family.

Figure 2

### 1.1.2.2 Bioactivity

The natural role of these marine metabolites was proposed to involve predation deterrence based on the results of mollusc and fish lethality assays. Their
mollusicidal and repellent activity against muricid gastropods, ichthyotoxicity, brine shrimp lethality and inhibition of the cell division in fertilised starfish eggs provides strong evidence that they are used by octocorals as defence against predators. Many of the cladiellins have also been shown to possess interesting pharmaceutical activities, with several compound reported to be antiinflammatory and anti-tumour agents. Sclerophytin A seems to be one of the most potent cladiellins and it was reported that this compound exhibits growth inhibitory activity against the murine L 1210 leukemia cell line with an $\mathrm{IC}_{50}=$ $1.0 \mathrm{ng} / \mathrm{mL} .^{7}$ Recently studies have shown that pachycladin A, sclerophytin $F$ methyl ether, polyanthelin A and sclerophytin A possess interesting prostate cancer invasion and migration inhibition (Figure 3). ${ }^{8}$

### 1.1.3 Previous Syntheses of Members of the Cladiellin Family

### 1.1.3.1 The Overman Group Approach

The Overman group was the first to report a total synthesis of a member of the cladiellin family with the synthesis of 7-deacetoxyalcyonin acetate in 1995. ${ }^{14}$ Since then, this group has reported the synthesis of two other members of this family: sclerophytin A and cladiell-11-ene-3,6,7-triol (Figure 5). ${ }^{15}$

7-Deacetoxyalcyonin acetate

Initially purported structure of sclerophytin A

Sclerophytin A

Cladiell-11-ene-3,6,7-triol

Figure 5

The disconnection used by Overman and co-workers in their planning of the synthesis of their target is show in Figure 6. The hydroisobenzofuran was to be formed via a Prins-pinacol condensation-rearrangement, and closure of the medium size ring was to be accomplished using a Nozaki-Hiyama-Kishi coupling.

Figure 6

The defining reaction in this synthesis is the diastereoselective Prins-pinacol condensation-rearrangement ${ }^{16}$ of dienyl diol 2 with aldehyde 3 , which proceeds through the chair-like transition state 5, to assemble the hydroisobenzofuran core of 7-deacetoxyalcyonin acetate 4 (Scheme 2).

Scheme 2

Overman achieved the total synthesis in 20 steps from (S)-glycidyl pivalate 8 with an overall yield of $4 \%$. The Prins-pinacol condensation-rearrangement precursor 10 was obtained by a convergent protocol, starting from (S)-carvone 6 and (S)-glycidyl pivalate 8 (Scheme 3). The key Prins-pinacol rearrangement reaction was achieved by exposure of diol 10 and an excess of enal 11 to $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$, giving the hexahydroisobenzofuran 12 as a single stereoisomer in $79 \%$ yield. After further functionalisations, the oxanane ring was fashioned by treating 13 with $\mathrm{NiCl}_{2}-\mathrm{CrCl}_{2}$ in DMSO following the Nozaki-Hiyama-Kishi procedure, ${ }^{17}$ to provide the tricyclic alcohol 14 in $65 \%$ yield. Finally, acetylation of 14 followed by cleavage of the silyl ether gave the natural product in $88 \%$ yield.

a) LDA, $\mathrm{PhN}(\mathrm{Tf})_{2}$; b) $\left(\mathrm{Me}_{3} \mathrm{Sn}\right)_{2}, \mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}, \mathrm{NIS}, 78 \%$ (2 steps); c) $t$-BuLi; d) PPTS, $\mathrm{MeOH}, 64 \%$ (2 steps); e) $\mathrm{BF}_{3} \bullet \mathrm{Et}_{2} \mathrm{O}, 79 \%$; f) $\mathrm{NiCl}_{2}-\mathrm{CrCl}_{2}, 65 \%$; g) $\mathrm{Ac}_{2} \mathrm{O}$, pyridine; h) TBAF, $88 \%$ (2 steps).

Scheme 3

Overman used the synthesis sclerophytin A as an opportunity to demonstrate that the strategy developed for the synthesis of 7-deacetoxyalcyonin acetate could be used to address the synthesis of other natural products of the same family containing either exocyclic or endocyclic unsaturation in the cyclohexane ring. ${ }^{18}$ They improved the synthesis by using (Z)-a,B-unsaturated aldehyde 15 (Scheme 4) containing one more carbon than that used during the original synthesis of the 7-deacetoxyalcyonin acetate. A two-step procedure, in which the enal 15 and dienyl diol 10 were combined to produce hydroisobenzofuran 17, was developed. Condensation of 10 with 15 using $p$-toluenesulfonic acid afforded acetal 16 as a mixture of diastereomers in $76 \%$ yield. Prins-pinacol rearrangement of 16 proceeded efficiently in the presence of a catalytic amount of $\mathrm{SnCl}_{4}$ to give the aldehyde 17 in $88 \%$ yield. At this point, all the carbon atoms of the target molecule were installed. After further modifications, the oxonene ring was formed by treating 13 with $\mathrm{NiCl}_{2}-\mathrm{CrCl}_{2}$, following the Nozaki-HiyamaKishi procedure, to provide tricyclic ether 14 in $61 \%$ yield. Compound 14 served as a common intermediate in the synthesis of 7-deacetoxyalcyonin acetate and
sclerophytin A. 7-Deacetoxyalcyonin acetate was obtained following the route previously reported. Completing the synthesis of the presumed structure of sclerophytin A required formation of a bridging tetrahydropyran ring between carbon C-3 and C-7. Desilylation of 14 and subsequent sequential treatment with $\mathrm{Hg}(\mathrm{OAc})_{2}$ and $\mathrm{NaBH}_{4}$ furnished the single tetracyclic diether 18 in $47 \%$ yield. Light-induced isomerisation of 18 was realised in high yield to give exocyclic alkene 19. However, when Overman and co-workers compared spectroscopic data of 19 with that reported for the natural product there were significant discrepancies. To investigate the possibility that sclerophytin A was epimeric at the hydroxyl-bearing stereogenic centre, the synthesis of the compound 20 from alcohol 19 was performed. However, the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra for compound 20 were distinctly different to those reported for the natural product.

a) $p-\mathrm{TsOH}, \mathrm{MgSO}_{4}, 76 \%$; b) $\mathrm{SnCl}_{4}, 88 \%$; c) $\mathrm{NiCl}_{2}-\mathrm{CrCl}_{2}, 61 \%$; d) $\mathrm{Ac}_{2} \mathrm{O}$, pyridine; e) TBAF, $88 \%$ (2 steps); f) TBAF; g) $\mathrm{Hg}(\mathrm{OAc})_{2}, \mathrm{NaBH}_{4}, \mathrm{NaOH}, 41 \%$ (2 steps); h) hv, 80\%; i) DMP; j) $\mathrm{NaBH}_{4} ; 75 \%$ (2 steps).

## Scheme 4

Further detailed spectroscopic studies of sclerophytin B, the monoacetate of sclerophytin A, published by Paquette and co-workers indicated that these substances were probably lacking the second ether bridge. ${ }^{19}$ This structural revision allowed the total synthesis of the natural product to be performed.

The Overman group obtained sclerophytin A using their previously reported synthetic methodology. Compound 14 was obtained form (S)-carvone in 17 steps and $6 \%$ overall yield (Scheme 5). Epoxidation of the exocyclic alkene of 14 afforded epoxy-alcohol 21 in very good yield. Subsequent epoxide opening and deprotection afforded cladiell-11-ene-3,6,7-triol, which underwent
photochemical isomerisation to give the revised structure of sclerophytin A. The NMR data of the compound, as well as the $[\alpha]_{\mathrm{D}}$, matched those of the natural product. ${ }^{15,20}$

a) $\mathrm{VO}(\mathrm{acac})_{2}$, TBHP, $95 \%$; b) DIBAL-H; c) TBAF, $75 \%$ (2 steps); d) hv, $28 \%$.

Scheme 5

The Overman group has continued its work on the synthesis of oxygen-bridged 2,11-cyclised cembranoids. This work has culminated in the recent total synthesis of two briarellins. ${ }^{21}$

### 1.1.3.2 The Paquette Group Approach

The Paquette group embarked on the total synthesis of the 2,11-cyclised cembranoids a few years after Overman. Paquette also completed a review of these natural products and their bioactivity. ${ }^{1}$ Concurrently to the Overman group, Paquette and co-workers undertook the challenge of synthesising sclerophytin A. Their strategy involved the formation of the hydroisobenzofuran ring using a Diels-Alder cycloaddition reaction and construction of the medium ring via a Claisen rearrangement reaction (Figure 7). ${ }^{22}$

Figure 7

The synthesis started with an intermolecular Diels-Alder cycloaddition reaction between the Danishesky diene 22 and lactone 23 to form the hydroisobenzofuran ring (Scheme 6). Further functionalisation of lactone 24 gave nitrile 25. Mild hydrolysis of the nitrile afforded a carboxylic acid which upon submission to Yamaguchi macrolactonisation conditions gave a separable mixture of lactone diastereomers. Both diastereomeric lactones were independently subjected to Tebbe methylenation to give the enol ether 26. Claisen rearrangement promoted by $\mathrm{NaBF}_{4}$ transformed cleanly both isomers of 26 into 27. The next stage of the synthesis involved the functionalisation of the cyclohexyl ring. This was achieved in eleven steps via an aldol reaction with formaldehyde and conjugate addition of an isopropyl group, both reactions occuring from the least hindered face. Finally, reductive removal of the carbonyl group gave 28. Formation of the fourth ring was achieved by oxymercuration and subsequent oxidative demercuration, giving a mixture of epimeric alcohols 29. The purported structure of sclerophytin A was obtained in three more steps. However, as observed by Overman and co-workers the spectroscopic data of 19 differed from that reported for the natural product. Oxidation and reduction of the secondary alcohol afforded the diastereomeric alcohol 20 the data for which did not match that for the natural product data either.

$d-f$

a) toluene; b) TMSOTf, pyridine; c) $\mathrm{NaBH}_{4}, \mathrm{CeCl}_{3}, \mathrm{MeOH}, 71 \%$ (3 steps); d) i) NaOMe , $\mathrm{H}_{3} \mathrm{O}^{+}$; ii) LiOH ; e) $\mathrm{Cl}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{COCl}, \mathrm{Et}_{3} \mathrm{~N}$, DMAP; f) $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{TiCH}_{2} \mathrm{CIAl}\left(\mathrm{CH}_{3}\right)_{2}, 52 \%$ (3 steps); g) $\mathrm{NaBF}_{4}, 75 \%$; h) $\mathrm{Hg}\left(\mathrm{OCOCF}_{3}\right)_{2}, \mathrm{O}_{2}, \mathrm{NaBH}_{4}, 54 \%(3: 7 \mathrm{dr})$; i) $\mathrm{Ac}_{2} \mathrm{O}$, pyridine; j) TBAF; k) o$\mathrm{NO}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{SeCN}, \mathrm{PBu}_{3}$, pyridine, $\mathrm{H}_{2} \mathrm{O}_{2}$; I) DIBAL-H, $73 \%$ (4 steps); m) ( $n$ - Pr$)_{4} \mathrm{NRuO}_{4}$, NMO; n) DIBAL-H, 90\% (2 steps).

Scheme 6

After extensive NMR studies on sclerophytin B, Paquette and co-workers proposed the reassignment of the structures of sclerophytins $A$ and $B$ to those lacking the second ether bridge. ${ }^{19}$ The synthesis of the new structure was achieved in 27 steps and $0.5 \%$ overall yield using the previous synthetic route (Scheme 7). Compound 30 was obtained in 22 steps from lactone 23. Upjohn dihydroxylation afforded the syn-diol 31. Oxidation of the secondary alcohol followed by deprotection and Grieco elimination of the primary alcohol gave hydroxyl-ketone 32. Concomitant removal of the tertiary benzoate and reduction of the ketone revealed the new structure of sclerophytin $A .^{20,} 23$ Spectroscopic data for this compound matched those reported for the natural product. Finally, selective acetylation of the secondary alcohol delivered sclerophytin B.

## Scheme 7

Following the synthesis of sclerophytin A and B, the Paquette group conducted further NMR studies on sclerophytin type diterpenes and proposed the structural or stereochemical reassignment of eight other natural products. ${ }^{6}$

### 1.1.3.3 The Molander Group Approach

Several years after the Overman synthesis of 7-deacetoxyalcyonin acetate, the Molander group divulged a strategically unique approach to the synthesis of this natural product. A [2+2] cycloaddition reaction followed by photochemical rearrangement formed the hydroisobenzofuran core common to all the cladiellins, which was further functionalised using a Lewis acid-mediated [4+3] annulation reaction (Figure 8). ${ }^{24}$

Figure 8

This annulative approach required a chemically differentiable 1,2-dialdehyde such as a bis-acetal to serve as a double-electrophile (Scheme 8). Upon exposure to a Lewis acid the bis-acetal 33 ionised selectively to give a single oxocarbenium ion 35 which underwent nucleophilic attack. A second ionisation, followed by cyclisation, resulted in the formation of the hydroisobenzofuran core 34 present in the cladiellin diterpenes in a single operation. The stereochemical outcome of the process is controlled by the attack of the nucleophile from the convex face of the bicyclic ionic intermediate.

Scheme 8

Molander and co-workers completed the total synthesis of 7-deacetoxyalcyonin acetate in 17 steps with an overall yield of $4 \%$ (Scheme 9). Starting from a-phelladrene 36, a [2+2] cycloaddition reaction followed by a photochemical rearrangement yielded the desired mixed acetal 33. This bis-acetal underwent $\mathrm{TiCl}_{4}$-mediated $[4+3]$ annulation with complete regio- and stereo-selectivity to form 34. Further functional group interconvertion delivered the aldehyde 37 precursor for the Nozaki-Hiyama-Kishi cyclisation reaction. Tetracyle 38 was obtained by protection of the secondary alcohol resulting from the Nozaki-Hiyama-Kishi coupling. Chemoselective epoxidation of the trisubstitued alkene, followed by oxidative cleavage of the allylic acetate with ozone and epoxide deoxygenation provided olefin 39. Finally, chemoselective silyl ether formation, Wittig olefination and cleavage of the silyl ether revealed a ketone which was diastereoselectively methylated to give 7-deacetoxyalcyonin acetate.

## Scheme 9

The Molander group investigated another approach to the synthesis of the cladiellins using a $\mathrm{Sml}_{2}$-mediated cyclisation instead of the Nozaki-Hiyama-Kishi coupling. However, this methodology failed to deliver any of the natural products giving only the 3,7-diastereomer of polyanthellin A. ${ }^{25}$

### 1.1.3.4 The Crimmins Group Approach

In 2004, Crimmins and co-workers reported the synthesis of the ophirin B and in 2006 they completed the synthesis of astrogorgin using the same synthetic strategy (Figure 8). ${ }^{26,27}$ Crimmins was the first to use a strategy where the hydroisobenzofuran unit was not incorporated prior to oxonene formation. The synthesis featured an intramolecular ring closing metathesis reaction for the formation of the oxonene followed by an intramolecular Diels-Alder cycloaddition reaction which afforded the cyclohexene. Ophirin B was obtained in 27 steps with an overall yield of $6 \%$.

Figure 9

The synthesis started with the reaction of (S)-benzylglycidyl ether 40 with dimethylsulfonium methylide delivering a secondary alcohol, which was protected prior to Wacker oxidation to form the methyl ketone 41 (Scheme 10). Further alkylation and protecting group modification delivered 42 in four steps. Reaction of the activated carboxylic acid with the oxazolidinone formed the compound 43, the key intermediate for the installation of the C-9 stereogenic centre via a diasteroselective alkylation. This centre was created with high diastereomeric excess >98:2. Removal of the chiral auxiliary gave the diene 45 which was submitted to ring-closing metathesis conditions. This cyclisation reaction proceeded in high yield using Grubbs $2^{\text {nd }}$ generation catalyst in benzene at reflux. With the cyclic ether in place, Crimmins and co-workers focused on the synthesis of the Diels-Alder precursor 47. This was prepared from 46 in 11 steps involving protecting group modifications, oxidation reactions and Wittig olefinations. The Diels-Alder reaction proceeded simply by allowing compound 47 to stand at room temperature. The tetraene 47 was rapidly converted into the desired tricyclic system 48 in high yield as a single diastereomer in about 2 hours.

41

a) $\mathrm{Me}_{3} \mathrm{SI}, n$-BuLi, $99 \%$; b) $\mathrm{NaH}, \mathrm{PMBCI}, 90 \%$; c) $\mathrm{Hg}(\mathrm{OAc})_{2}, \mathrm{H}_{2} \mathrm{O}, \mathrm{PdCl}_{2}, \mathrm{LiCl}, \mathrm{CuCl}_{2}, \mathrm{H}_{2} \mathrm{O}$, $\mathrm{O}_{2}, 89 \%$; d) $\mathrm{Me}_{3} \mathrm{CCOCl}, \mathrm{Et}_{3} \mathrm{~N},(\mathrm{~S})$-lithio-4-isopropyloxazolidin-2-one, 89\%; e) NaHMDS, $\mathrm{CH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{l}, 93 \%$; f) $\mathrm{LiBH}_{4}, \mathrm{MeOH}, 92 \%$; g) Grubbs $2^{\text {nd }}$ Gen., 15:1 oxonene:dimer, 89\%; h) THF, 78\%.

Scheme 10

The original end game of the synthesis involved the formation of the triol 49 which would then undergo acetylation to afford the natural product. However, all attempts to form the triacetate ophirin B directly from the triol 49 were thwarted by the formation of the bridged ether 50 (Scheme 11). A wide range of standard or Lewis acid catalysed acetylation reactions were tested, but these produced either the tetracyclic alcohol 50 or resulted in decomposition of the triol 49. Crimmins and co-workers postulated that the sterically less hindered $\mathrm{C}-13$ secondary alcohol underwent acetylation first. The axial orientation of the C-15 hydroxypropyl group suitably positioned the hydroxyl group for allylic displacement of the $\mathrm{C}-13$ allylic acetate.

a) $\mathrm{MeMgCl}, 85 \%$; b) TBAF, $94 \%$; c) Na naphthalene, $90 \%$; d) $\mathrm{Ac}_{2} \mathrm{O}$, DMAP, pyridine.

Scheme 11

To achieve the synthesis of the ophirin B, Crimmins and co-workers firstly acetylated the C-15 hydroxypropyl group of 51 in order to suppress the formation of the bridged ether (Scheme 12). Lewis acid catalysed acetylation then afforded the bis-acetate 52. Careful hydrogenolysis of the C-13 benzyl ether and subsequent acetylation afforded the natural product ophirin B.

51

52

Ophirin B
a) $\mathrm{KH}, \mathrm{Ac}_{2} \mathrm{O}, 90 \%$; b) $\mathrm{Bi}(\mathrm{OTf})_{3}, \mathrm{Ac}_{2} \mathrm{O}, 75 \%$; c) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}, 70 \%$; d) $\mathrm{Ac}_{2} \mathrm{O}$, DMAP, pyridine, $95 \%$.

Scheme 12

The synthesis of the cladiellin astrogorgin was completed using the same general strategy. The two routes diverge from the compound 43 (Scheme 13). Asymmetric alkylation with the allylic iodide 53 provided the diene 54 in excellent yield. Ring-closing metathesis followed by further functional transformations gave the Diels-Alder precursor 55. As was the case for the ophirin B intermediate, when the tetraene 55 was allowed to stand at room temperature it was converted to the desired oxatricyclic compound 56 in high yield, which was converted into the natural product in several steps.

54

55

a) $\mathrm{NaHMDS}, 90 \%$.

Scheme 13

As well as completing the synthesis of the cladiellins ophirin B and astrogorgin, the Crimmins group have synthesised other oxygen-bridged 2,11-cyclised cembranoids. They have reported, the synthesis of the asbestinins 11-acetoxy-4deoxyasbestinin $D$ and asbestinins-12, ${ }^{28,29}$ as well as the proposed structure of briarellins J using the same methodology. ${ }^{30}$

### 1.1.3.5 The Kim Group Approach

Recently, Kim and co-workers reported the first total synthesis of an E-cladiellin diterpene, cladiella-6,11-dien-3-ol. ${ }^{31}$ The significance of this compound is that it can be easily transformed into other members of the cladiellin diterpene family, such as polyanthellin A, cladiell-11-ene-3,6,7-triol, and deacetoxyalcyonin acetate (Figure 10). The strategy used by Kim and co-workers featured an intramolecular amide enolate alkylation reaction and an intramolecular Diels-Alder cycloaddition.

Polyanthellin A

Cladiell-11-ene-3,6,7-triol
Figure 10

Cladiella-6,11-dien-3-ol was obtained in 21 steps with an overall yield of $6 \%$, starting from a glycolate oxazolidinone 57 and 5 -methylhex-4-enal 58 (Scheme 14). Aldol addition followed by protective group modification gave 59 . An additional deprotection and $O$-alkylation provided the desired amide. Stereoselective allylic oxidation with selenium dioxide furnished the corresponding allylic alcohol which was chlorinated under standard condition to deliver the E-allylic chloride 60. Intramolecular amide enolate alkylation of 60 led to the formation of the desired cis- $E$-oxonene 62 as a single diastereomer in excellent yield, presumably through the lithiated intermediate 61. Compound 62 was converted into the required Diels-Alder precursor 63 over several steps. Intramolecular Diels-Alder cycloaddition afforded product 64 in good yield when 63 was heated at reflux in xylene with butylated hydroxytoluene (BHT). Double methylation of the ester followed by dissolving metal reduction delivered the isopropyl moiety 65. Finally, introduction of the C-3 methyl produced cladiella-6,11-dien-3-ol.

a) $n-\mathrm{Bu}_{2} \mathrm{BOTf}, \mathrm{Et}_{3} \mathrm{~N}, 75 \%, 98: 2 \mathrm{dr}$; b) $\mathrm{NaBH}_{4}, 89 \%$; c) TBDPSCI, imidazole, $92 \%$; d) trityl bromide, DMAP, pyridine, $93 \%$; e) DDQ, $88 \%$; f) $\mathrm{ClCH}_{2} \mathrm{CONMe}_{2}, \mathrm{NaH}, 88 \%$; g) $\mathrm{SeO}_{2}$, pyridine, $\mathrm{NaBH}_{4}, \mathrm{EtOH}, 76 \%$; h) $\mathrm{PPh}_{3}, \mathrm{CCl}_{4}$, pyridine, $93 \%$; i) LiHMDS, $92 \%$; j) BHT, xylene reflux, $85 \%$; k) MeLi, $\mathrm{CeCl}_{3}, 89 \%$; I) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{DMAP}, \mathrm{Et}_{3} \mathrm{~N} ; \mathrm{m}$ ) K,18-crown-6, $t$ - $\mathrm{BuNH}_{2}, 62 \%(2$ steps); n) DMP, o) MeLi, $\mathrm{NaBF}_{4}, 82 \%$ (2 steps).

Scheme 14

Cladiella-6,11-dien-3-ol can be used as an advanced intermediate for the synthesis of several other members of the cladiellin family as shown in Scheme 15. Only two steps were necessary to obtain polyanthellin A from cladiella-6,11-dien-3-ol. First, a one-pot protocol of sequential oxymercuration and demercuration furnished the tertiary alcohol deacetylpolyanthellin A. Simple acetylation gave then polyanthellin A. Cladiell-11-ene-3,6,7-triol was readily obtained by treatment of cladiella-6,11-dien-3-ol with osmium tetroxide and 7-deacetoxyalcyonin acetate was obtained in 5 steps from cladiella-6,11-dien-3ol by sequential dihydroxylation, hydroxyl protection and elimination.

Scheme 15

### 1.1.3.6 The Clark Group Approach

The Clark group has been interested in the synthesis of the cladiellin natural products for some time, ${ }^{32}$ and in 2007 reported the total synthesis of vigulariol in the racemic form (Figure 11). ${ }^{33}$ This natural product was isolated from the octocoral Vigularia juncea by Sheu and co-workers and was found to possess in vitro cytotoxicity against A 549 (human lung adenocarcinoma) cell culture system with an $\mathrm{IC}_{50}$ of $18 \mu \mathrm{~g} / \mathrm{mL} .{ }^{34}$ Vigulariol possesses an additional ring in comparison to most of the other cladiellins. The synthesis was completed in 20 steps with an overall yield of $4 \%$ and featured three key ring formation reactions. The first being a $\mathrm{Sml}_{2}$ mediated cyclisation to prepare the key tetrahydropyranyl alcohol (Scheme 16). The second used a copper carbenoid to deliver a bicyclic oxonium ylide which then rearranged to give the oxabicyclico[6.2.1]undecene system. Finally a highly regioselective intermolecular Diels-Alder cycloaddition reaction constructed the cyclohexane ring.

Figure 11

Grignard reaction of the TBS protected bromo-propanol 67 with methacrolein delivered an allylic alcohol (Scheme 16). O-alkylation of the allylic alcohol followed by removal of the silyl ether protecting group and oxidation of the resulting alcohol gave the aldehyde precursor 68 required for the samarium mediated ring formation. The tetrahydropyranol 69 was obtained as a single diastereoisomer by reductive cyclisation using freshly prepared $\mathrm{Sml}_{2}$ in the presence of methanol. Protection of the hydroxyl group as a TBS ether and cleavage of the ethyl ester furnished the carboxylic acid, which was activated as a mixed anhydride and then treated with an excess of diazomethane to afford diazoketone 70. Treatment of 70 with copper(II) hexafluoroacetylacetonate produced an electrophilic copper carbenoid and then an oxonium ylide 71 or its metal-bound equivalent that underwent a [2,3]-sigmatropic rearrangement with three-carbon ring expansion. The reaction delivered a $5: 1$ mixture of bicyclic ketones 73 and 72 . The $E$-isomer $\mathbf{7 2}$ could be converted into the $Z$-alkene $\mathbf{7 3}$ by treatment with AIBN and ethanethiol.

a) Mg , methacrolein, $90 \%$; b) $\mathrm{HCCCO}_{2} \mathrm{Et}$, N -methylmorpholine, $91 \%$; c) TBAF, $91 \%$; d) $(\mathrm{COCl})_{2}, \mathrm{DMSO}, \mathrm{Et}_{3} \mathrm{~N}, 83 \%$; e) $\mathrm{Sml}_{2}, \mathrm{MeOH}, 76 \%$; f) TBSCl, imidazole, $91 \%$; g) $\mathrm{LiOH}, 82 \%$; h) i) $i$ - $\mathrm{BuO}_{2} \mathrm{CCl}, \mathrm{Et}_{3} \mathrm{~N}$, ii) $\mathrm{CH}_{2} \mathrm{~N}_{2}, 81 \%$; i) $\mathrm{Cu}\left(\mathrm{CF}_{3} \mathrm{COCHCOCF}_{3}\right)_{2}(5 \mathrm{~mol} \%), 96 \% 5: 1 \mathrm{Z}: E$; j) AIBN, EtSH, 56\%.

Scheme 16

With bicyclic ketone 73 in hand, the next goal was the formation of the third ring (Scheme 17). The unstable diene 74 was formed by Stille cross-coupling and was immediately subjected to Diels-Alder cycloaddition with methyl vinyl ketone. The reaction was both highly regio-selective and exhibited high facial diastereoselectivity on the diene to deliver a $2: 1$ mixture of exo and endo diastereoisomers. Isomerisation of the endo:exo mixture with potassium carbonate delivered uniquely the required ketone exo-75 (exo adduct). Wittig olefination formed the exocyclic alkene and cleavage of the enol ether under acidic condition revealed the ketone 76. Chemoselective hydrogenation of the exocyclic alkene and subsequent ketone methylenation furnished the diene 77. Removal of the silyl ether protecting group and Dess-Martin oxidation gave the corresponding ketone, which was treated with methylmagnesium chloride to install the C-3 methyl group affording the desired tertiary alcohol 78 as single diastereomer. Regioselective and stereoselective alkene epoxidation and subsequent nucleophilic epoxide opening with the tertiary hydroxyl group was achieved in a single step using m-CPBA, which to completed the synthesis of vigulariol.

a) $\mathrm{PhN}(\mathrm{Tf})_{2}, \mathrm{NaHMDS}$; b) $\mathrm{CH}_{2} \mathrm{C}(\mathrm{OEt}) \mathrm{SnBu}_{3}, \mathrm{LiCl}, \mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$; c) methyl vinyl ketone, $67 \%$ (3 steps); d) $\mathrm{K}_{2} \mathrm{CO}_{3}, 87 \%$; e) $\mathrm{Ph}_{3} \mathrm{PCH}_{3} \mathrm{Br}, t$-BuOK, $85 \%$; f) $\left.\mathrm{HCl}, 86 \% ; \mathrm{g}\right) \mathrm{H}_{2}, \mathrm{PtO}_{2}, 81 \%$; h) $\mathrm{Ph}_{3} \mathrm{PCH}_{3} \mathrm{Br}, t$-BuOK, $98 \%$; i) TBAF, $84 \%$; j) DMP; k) MeMgCl, $89 \%$ (2 steps); I) $m$-CPBA, $69 \%$.

Scheme 17

### 1.1.3.7 The Hoppe Group Approach

Recently, Hoppe and co-workers reported an asymmetric total synthesis of vigulariol. ${ }^{35}$ The synthesis was completed in ten steps with an overall yield of $5 \%$ from enantiomerically pure starting material. The principal features of the synthesis were an asymmetric homoaldol reaction and a ring-closing methathesis to form the medium sized ring (Figure 12).

Figure 12

Hoppe and co-workers were able to obtain their starting material, $(R)$-cryptone 79, in $97 \%$ ee by flash chromatography of eucalyptus oil (Scheme 18). This compound was then reduced with $\mathrm{LiAlH}_{4}$ to yield cycloalkenol 80 , which gave 81
after carbamoylation. Enantiomerically pure diol 82 was selectively protected and oxidised to afford the aldehyde coupling partner 84.

a) Flash column chromatography, (97\% ee); b) $\mathrm{LiAlH}_{4}$, (84:16 dr); c) $\mathrm{NaH}, i-\mathrm{Pr}_{2} \mathrm{NC}(\mathrm{O}) \mathrm{CI}$, $78 \%$ (97\% ee); d) TESCI, imidazole, $99 \%$; e) $\mathrm{BnOC}(\mathrm{NH}) \mathrm{CCl}_{3}, \mathrm{~F}_{3} \mathrm{CSO}_{3} \mathrm{H}, 86 \%$; f) DMSO, $(\mathrm{COCI})_{2}$, DIPEA, $81 \%$.

## Scheme 18

The two fragments, 81 and 84, were then coupled to give the alcohol 86 (Scheme 19). This was achieved by stereospecific deprotonation using s-BuLi and $N, N, N$ ',$N^{\prime}$-tetramethyl-1,2-diaminocyclohexane, subsequent lithiumtitanium exchange using $\mathrm{ClTi}(\mathrm{Oi}-\mathrm{Pr})_{3}$ and trapping with fragment 84 to give the required diastereomer 86 in just $33 \%$ yield. Condensation with acetal 87 provided diene 88. The tricyclic core of vigulariol was formed by ring closing metathesis using Grubbs $2^{\text {nd }}$ generation catalyst. The resulting alkene 89 was subjected to epoxidation before the removal of the benzyl protecting group revealed the tertiary alcohol, which underwent rapid and stereospecific attack onto the epoxide moiety. Finally, the natural product was obtained by Wittig methylenation of the ketone.

Scheme 19

### 1.1.3.8 The Johnson Group Approach

The Johnson group recently reported the synthesis of polyanthellin A in 15 linear steps and $2 \%$ overall yield. ${ }^{36}$ Their strategy featured the formation of the hydroisobenzofuran via a [3+2] cyclopropane - aldehyde cycloaddition reaction and the construction of the oxonane ring by ring-closing metathesis (Figure 13).

Polyanthellin A
Figure 13

The cyclopropane 96 and aldehyde 92 adducts required for the key cycloaddition reaction were synthesised in five and six steps respectively (Scheme 20). Sharpless epoxidation of the methallyl alcohol 90 was followed by opening of the epoxide using allyl cuprate. One-carbon homologation and
protection of the tertiary alcohol afforded aldehyde 92. Enantioselective organocatalytic conjugate addition of isovaleraldehyde 93 to methyl vinyl ketone gave 94. Olefination of the aldehyde gave the diene and carboalkoxylation revealed the ketoester 95 . The formation of the cyclopropane 96 was obtained via a two-step protocol through a diazo carbonyl compound.

a) $\mathrm{Ti}(\mathrm{Oi}-\mathrm{Pr})_{4},(-)-\mathrm{DET}, \mathrm{TBHP}, 69 \% ;$ b) $\mathrm{Li}_{2} \mathrm{CuCl}_{4}, \mathrm{AllyIMgCl}, 77 \%$; c) $p-\mathrm{TsCl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP} ;$ d) KCN; e) TMSCI, imidazole, $76 \%$ (3 steps); f) DIBAL-H, 68\%; g) MVK, 97, 98, 90\%; h) $\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{CHCH}_{2}, t$-BuLi, Ti(Oi-Pr) 4 , Mel, 71\%; i) LiTMP, HMPA, MeOC(O)CN, 72\%; j) $p$ $\mathrm{AcHNC}_{6} \mathrm{H}_{4} \mathrm{SO}_{2} \mathrm{~N}_{3}, \mathrm{Et}_{3} \mathrm{~N} ; \mathrm{k}$ ) 99, $71 \%$ (2 steps).

Scheme 20

The cycloaddition of aldehyde 92 and cyclopropane 96 proved problematic but after Lewis acid screening Johnson and co-workers found that the use MADNTf ${ }_{2}$ as a catalyst formed in situ from 103 and $\mathrm{HNTf}_{2}$ afforded the hydroisobenzofuran 100 in $76 \%$ yield and good diastereoselectivity (Scheme 21). Further ring-closing metathesis and Krapcho decarboxylation gave the cladiellin skeleton 101. Direct hydroboration and TPAP oxidation of alkene 101 afforded the corresponding ketone, which underwent double Wittig olefination to yield diene 102. Finally a three-step protocol involving iodoetherification, oxymercuration and reduction delivered deacetylpolyanthellin $A$ as a $6: 1$ mixture of diastereomers. Both diastereomers were acetylated under standard condition to deliver polyanthellin A.

Scheme 21

### 1.1.3.9 The Morken Group Approach

Recently the Morken group published a concise synthesis of sclerophytin A in 13 steps and $2.7 \%$ yield from geranial using a new route. ${ }^{37}$ Their strategy is unique because it involves the synthesis of the furan ring first using the Oshima-Utimoto reaction, ${ }^{38}$ then the formation of the hydroisobenzofuran via a radical cyclisation reaction and finally oxonene formation by ring-closing metathesis (Figure 14).

Figure 14

The synthesis started with a Brown methallylation of geranial 104 giving alcohol 105 with $98 \%$ ee (Scheme 22). Oshima-Utimoto reaction formed the furan ring,
subsequent Jones oxidation delivered the lactone and $a$-iodination yielded the cyclisation precursor 106. $\mathrm{InCl}_{3}$ and $\mathrm{NaBH}_{4}$ mediated reductive radical cyclisation delivered the hydroisobenzofuran moiety which was reduced to the lactol 108. Three straight forward steps delivered the triene 109. The tricyclic core 110 was obtained by ring-closing metathesis using Grubbs $2^{\text {nd }}$ generation catalyst subsequent chemoselective epoxidation of the trisubstituted alkene gave a 1.8:1 mixture of 111:112.

a) $(\mathrm{lpc})_{2} \mathrm{~B}, 92 \%$; b) $\mathrm{Pd}(\mathrm{OAc})_{2}, \mathrm{Cu}(\mathrm{OAc})_{2}, \mathrm{CH}_{2} \mathrm{CHOC}\left(\mathrm{CH}_{3}\right)_{3}, 62 \%$; c) $\mathrm{H}_{2} \mathrm{CrO}_{4}, 68 \%$;

Scheme 22

Treatment of the mixture of 111 and 112 with LiOH and then $\mathrm{Sc}(\mathrm{OTf})_{3}$ resulted in the formation of the hemiketal 113 which upon reaction with methyl magnesium chloride afforded sclerophytin A (Scheme 23).

a) i) LiOH ; ii) $\mathrm{KHSO}_{4}, \mathrm{Sc}(\mathrm{OTf})_{3}, 88 \%$; b) $\mathrm{MeMgCl}, 99 \%$.

Scheme 23

The cladiellin family of natural products have interested many synthetic research groups over the past fifteen years. ${ }^{39}$ The synthesis of these natural products has enabled many research groups to test and prove the utility of their methodology. However, only Kim and co-workers have reported the synthesis of an E-cladiellin and have developed a general route that is applicable to the synthesis of many members of the family.

### 1.2 Radical Cyclisation Reactions

Radical reactions, and in particular radical cyclisations, are very important tools for organic chemists. The scope of these reactions is very wide, and the focus herein will be on the formation of oxacycles using $B$-alkoxyacrylates as acceptors in intramolecular radical cyclisation reactions.
Araki and co-workers first reported such reaction in 1989 for the synthesis of higher-carbon sugars. ${ }^{40}$ The cyclisation of terminal halogenofuranoses bearing an O-alkoxycarbonyethenyl group proceeded in good yield when they were treated with tributyl tin hydride and AIBN as radical initiator (Scheme 24). Five and sixmembered rings were formed diasteroselectively (115 and 117) when the substituents were orientated favourably. However, mixtures of diastereomers 119 and 120 were obtained when the substituents were orientated less favourably, as in bromide 118. Four- and seven-membered oxacycles were also obtained using these conditions, as mixtures of diastereomers.

$119 \mathrm{R}^{1}=\mathrm{H}, \mathrm{R}^{2}=\mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{Et}$ $120 R^{1}=\mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{Et}, \mathrm{R}^{2}=\mathrm{H}$ mixture 119:120 5:1

Scheme 24

Some years later Lee and co-workers studied the synthesis of tetrahydrofurans and tetrahydropyrans and reported that B-alkoxyacrylates were exceptionally efficient radical acceptors in radical mediated intramolecular cyclisation reaction. ${ }^{41}$ These workers demonstrated that both five- and six-membered cyclic ethers can be obtained in high yield and with complete exo-selectivity, starting from halogenoalkane bearing a $B$-alkoxyacrylate (Scheme 25). They postulated that the exo-selectivity is due to the large orbital coefficient at the $B$-carbon in the LUMO of the $B$-alkoxyacrylate. The reaction was also found to exhibit cis-selectivity, forming cis-2,5-disubstituted tetrahydrofuran 125 and cis-2,6-disubstituted tetrahydropyran 126, which can be explained by formation of a chair-like transition state.

Lee and co-workers then studied the radical cyclisation of $B$-alkoxyacrylates with stannyloxyalkyl radicals, forming oxacyclic rings bearing a secondary hydroxyl group (Scheme 26). ${ }^{42}$ Hydroxyl-substituted tetrahydrofurans and tetrahydropyrans were formed in high yield but in each case two diastereomers were observed, meaning that the two transition states 136 and 138 possess similar energies. However, only cis-2,6-disubstitued tetrahydropyranyls were isolated, confirming the chair-like transition state postulated previously.

Scheme 26

Even though the reaction conditions needed to be developed to give a more diastereoselective cyclisation, Lee and co-workers showed that this methodology could be used in an iterative manner by building fused bicyclic ethers 141 and 142 in 9 steps (Scheme 27). ${ }^{42}$

a) $\mathrm{Bu}_{3} \mathrm{SnH}, \mathrm{AIBN}, 42 \%$ of 129 ; b) $\mathrm{Bu}_{3} \mathrm{SnH}, \mathrm{AIBN}, 23 \%$ of $141,72 \%$ of 142.

Concurrently the Evans group worked on the synthesis of 5-, 6-, 7-membered cyclic ethers via radical cyclisation using acyl selenide and $B$-alkoxyacrylate. ${ }^{43}$ Tetrahydrofuran-3-ones, tetrahydropyran-3-ones and oxepan-3-ones were obtained in high yields and good cis-selectivities (Table 2). However, the lower diastereoselectivity of this reaction compare to alkyl radical cyclisation made it less attractive.

Method $\mathrm{A}: \mathrm{Ph}_{3} \mathrm{SnH}, \mathrm{Et}_{3} \mathrm{~B}$, benzene, reflux; $\mathrm{B}:(\mathrm{TMS})_{3} \mathrm{SiH}, \mathrm{Et}_{3} \mathrm{~B}$, benzene, rt.
Table 2

Nakata and co-workers developed new conditions for Lee's radical cyclisation of aldehydes with $B$-alkoxyacrylates, forming hydroxy-tetrahydropyrans. ${ }^{44}$ The use of $\mathrm{Sml}_{2}$ for the reductive intramolecular cyclisation of aldehydes or ketones compound with a,b-unsaturated esters had already been developed for the formation of carbocycles. ${ }^{45}$ Nakata and co-workers used $\mathrm{Sml}_{2}$ for the reductive formation of hydroxy-tetrahydropyrans with great success (Scheme 28). The reaction proceeded in excellent yield and complete stereoselectivity, allowing the construction of the trans-fused polyether 152 in an iterative fashion. Only four different reactions were needed for the synthesis of tetracycle 152 from 146. The cyclisation reaction giving 148 is thought to proceed via the transition state 153 , which is generated by initial single-electron reduction of the aldehyde with $\mathrm{Sml}_{2}$ and chelation of the samarium(III) to the ester. The resulting ketyl radical attacks the $B$-position of $B$-alkoxyacrylate giving 154 , which is then reduced to an anion by a second equivalent of $\mathrm{Sml}_{2}$ and finally protonated by MeOH to give the corresponding 2,3 -trans-tetrahydropyran 148 . The chelation of
the samarium(III) to the ester contributes to the high diastereoselectivity of the reaction. This explains the lower diastereoselectivity obtained in cases where this chelation is absent, such as when $\mathrm{Bu}_{3} \mathrm{SnH}$ is used to generate a radical.

a) ethyl propiolate, N -methylmorpholine; b) Mel, aqueous MeCN ; c) $\mathrm{Sml}_{2}$, MeOH ; d) DIBAL-H;
e) 1,3-propanedithiol, $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$.

## Scheme 28

Oxepane rings were also obtained diastereoselectively using this samariummediated reaction (Scheme 29). ${ }^{46}$ However, the cyclisation reaction was always accompanied by lactonisation in this case. The reaction proceeded via the transition state 158 in which the chelation of samarium to the ester would explain the 2,3-trans selectivity. Tetracycle 157 was obtained using an iterative strategy based on the $\mathrm{Sml}_{2}$ inducted cyclisation.

This iterative protocol was an important innovation for the synthesis of polycyclic ethers. In 2004 the Nakata group was able to complete the synthesis of brevetoxin B using this methodology. ${ }^{47}$ The synthetic route featured $\mathrm{Sml}_{2}$-mediated oxepane ring formation to construct the D ring 161 (Scheme 30). Subsequently, a bi-directional synthetic strategy, using a ketone instead of an aldehyde afforded the C and E rings bearing a methyl group 163. Brevetoxin B was obtained with a longest linear sequence of 59 steps and the route showcased the utility of this cyclisation.

a) $\mathrm{Sml}_{2}, \mathrm{MeOH}, 83 \%$; b) $\mathrm{Sml}_{2}, \mathrm{MeOH}$; c) $p-\mathrm{TsOH}, 79 \%$ (2 steps).

Scheme 30

Over the last twenty years the development of the $\mathrm{SmI}_{2}$-mediated cyclisation reaction has resulted in a facile, efficient and diastereoselective route for the formation of cyclic ethers.

### 1.3 Chemistry of $a$-Diazo Carbonyl Compounds

Since the first synthesis of an a-diazo ester, ethyl diazoacetate, by Curtius in $1883,{ }^{48} a$-diazo carbonyl compounds have been the centre of attention of many chemists. ${ }^{49}$ The growing interest in this type of compound can be explained by the vast number of transformations they can undergo, as well as the development of more efficient methods for their synthesis. Moreover since the 70's and the introduction of dirhodium catalysts to generate carbenoids from diazo compounds, the opportunities for highly chemoselective transformations
have increased. ${ }^{50}$ In addition the introduction of chiral catalysts to promote asymmetric transformations of $a$-diazo carbonyl compounds has provided new possibilities.

### 1.3.1 Formation of a-Diazo Carbonyl Compounds

Curtius reported the first preparation of an a-diazo carbonyl compound by diazotisation of natural $a$-amino acids. ${ }^{48}$ Since then, various other methodologies for the preparation of a-diazo carbonyl have been developed. Acylation of diazomethane with an acyl chloride or an anhydride is the most common method for the synthesis of acyclic terminal $a$-diazo carbonyl compounds. The diazo group transfer technique, which enables the formation of both terminal and nonterminal systems, also occupies an important place in the $a$-diazo carbonyl preparation.

A common synthesis of diazoketones involves reaction of an acyl chloride 165 with at least two equivalents of diazomethane (Scheme 31). ${ }^{51}$ This excess of diazomethane is crucial as it reacts with the hydrogen chloride formed during the reaction and thereby prevents its addition to the diazoketone. Anhydrides 166 are also suitable acylating agents for diazomethane. ${ }^{52}$ A convenient method involves the in situ generation of a mixed anhydride 166 by the reaction of a carboxylic acid 164 with a chloroformate, followed by treatment with ethereal diazomethane. This is the method of choice in cases where the formation of an acid chloride would not be possible due to the presence of other reactive functional groups. For example, diazoketone 169 containing a sensitive epoxide was synthesised by this route. ${ }^{52}$

Scheme 31

The diazo transfer method was first developed to address the problem of the synthesis of cyclic a-diazo carbonyl compounds which are not accessible by acylation reactions. It is a general method that is widely used not only for the synthesis of cyclic compounds. Diazo transfer refers to the transfer of a complete diazo group from a diazo donor, generally a sulfonyl azide, to an acceptor, which for $a$-diazo carbonyl products are carboxylic acid or ketone derivatives. The acceptors can be divided into two different categories, those in which the $a$-methylene position is sufficiently reactive towards diazo transfer, and those that require prior activation to facilitate the transfer reaction. Malonic esters, $B$-ketoester, $B$-ketoamides and $B$-diketones are sufficiently reactive to react directly with tosyl azide using a weak base such as triethylamine (Scheme 32, eq 1). ${ }^{53}$ One technique that is used when prior activation is required is Regitz deformylating diazo transfer. ${ }^{54}$ This procedure involves Claisen condensation of the ketone with ethyl formate to introduce the strongly activating formyl group, which is later released as sulphonamide during the diazo transfer reaction (eq 2). Danheiser and co-workers modified the Regitz procedure in order to synthesise base sensitive $a$-diazo carbonyls by using the trifluoroacetyl group as an activator (eq 3). ${ }^{55}$ This allows milder coupling conditions to be employed than in the case of the Claisen condensation reaction.

$\mathrm{R}^{1}, \mathrm{R}^{2}=$ aryl, alkyl, $O$-alkyl, $O$-aryl, $\mathrm{NR}_{2} ; \mathrm{R}^{3}=\mathrm{Me}, p$-tolyl, $p$ - $\mathrm{CO}_{2} \mathrm{H}$-phenyl; $\mathrm{R}^{4}=$ aryl, alkyl.

### 1.3.2 Metal Carbenoid Formation

Free carbenes are very reactive species, but their utility for organic chemists is diminished by the methods required for their generation (usually thermal or photochemical) and their high reactivity that causes low selectivity and instability. Transition metals have been found to stabilise these carbenes and attenuate their reactivity thus increasing their synthetic utility. Metal carbenes are usually generated by the reaction of diazo compounds with transition metals, resulting in the production of complexes commonly referred to as metal carbenoids. Metal carbenoid mediated transformations usually display higher yield and selectivity that the corresponding free carbene transformations. The generally accepted mechanism for catalytic decomposition of diazo compounds starts with the nucleophilic addition of the diazo compound 170 to the metal complex, followed by the loss of nitrogen gas to form the metal-stabilised carbene or metal carbenoid 172 (Scheme 33). ${ }^{49}$ Transfer of the electrophilic carbene species to an electron-rich substrate ( S :) regenerates the catalyst and completes the catalytic cycle. Spectroscopic evidence for the formation of the diazonium adduct 171 has been obtained thanks to studies on the decomposition of diazo compounds with iodorhodium(III) tetra-p-tolylporphyrin, generating a spectroscopically stable (porphyrinatorhodium)-diaminocarbene complex. ${ }^{56}$

Scheme 33

Transition metals that are effective catalysts for diazo decomposition are Lewis acidic in character. ${ }^{49}$ Their catalytic activities are due to coordinative unsaturation at the metal centre, which allow them to react as electrophiles with diazo compounds. The metal used as well as the ligands have a profound effect on the regio-, chemo- and stereo-selectivity of the reaction. The first example of a metal-carbenoid reaction was described in 1906 when copper dust was used for the decomposition of ethyl diazoacetate. ${ }^{57}$ Copper remained the metal of choice for the decomposition of diazo compounds until the late 1970's and the discovery of rhodium(II) acetate dimer. ${ }^{50}$ This air stable catalyst became the single most widely used catalyst for metal carbenoid transformations. The most common complexes used for carbene generation are those of copper and rhodium but cobalt, palladium, ruthenium, osmium, iron, platinum and nickel compounds have also been used successfully. ${ }^{49}$

### 1.3.3 Metal Carbenoid Reactions

As previously discussed, metal carbenoids are synthetically useful because they are a less reactive versions of free carbenes. A large range of reactions can be performed with these compounds. The most widely studied metal-catalysed reaction of $a$-diazo carbonyl compounds is certainly cyclopropanation (Scheme 34). This is the reaction of a metal carbenoid with an alkene to generate a cyclopropyl group. It has been developed as both an inter- and intramolecular reaction and asymmetric variants are known. Other transformations, such as ylide formation and insertion reactions can also be observed. Insertion reactions can be obtained with $\mathrm{C}-\mathrm{H}, \mathrm{O}-\mathrm{H}, \mathrm{S}-\mathrm{H}, \mathrm{N}-\mathrm{H}$, and $\mathrm{Si}-\mathrm{H}$ bonds but the most synthetically valuable transformation is the $\mathrm{C}-\mathrm{H}$ bond insertion, because a new C-C bond is created. Ylides are formed by the attack on the metal carbenoid by nucleophiles lacking acidic protons, such as ethers, tertiary amines and thioethers leading to oxonium, ammonium and sulfonium ylides respectively. These ylides can then undergo further reactions such as [1,2]-Stevens shift, [2,3]-sigmatropic rearrangement, and to a lesser extent [1,4]-shift and $B$-elimination.

Although metal carbenoids can undergo a wide range of reactions, the focus of this thesis will be on the formation of oxonium ylides and their subsequent rearrangement.

### 1.4 Oxonium Ylide Generation and Rearrangement

Unlike ammonium and sulfonium ylide systems which are stable and have been well studied, free oxonium ylides are not isolable intermediates. For many years, metal catalysed reactions between $a$-diazo carbonyl compounds and ethers were thought to proceed by direct C-O insertion. ${ }^{58}$ However, conclusive evidence suggested that these reactions proceeded through formation and rearrangement of an oxonium ylide. This was deduced from the isolation of [2,3]-sigmatropic rearrangement products from reactions of allylic substrates that were analogous to those obtained from allylic sulfonium, ammonium and phosphonium ylides (Scheme 35). Over the past decade, the development of mild catalytic methods for the preparation of those oxonium ylides has resulted in a dramatic increase in their study and synthetic use. However, some questions remain about the exact identity of the ylide intermediate. Some evidence suggests that in certain cases rearrangement proceeds through a metal-bound intermediate rather than a free oxonium ylide. Nevertheless, in most cases the intermediate can be regarded as if it were a free oxonium ylide.

Scheme 35

### 1.4.1 The [1,2]-Stevens Shift

One of the first examples of oxonium ylide formation and subsequent [1,2]-Stevens shift was reported by Nozaki and co-workers (Scheme 36). ${ }^{59}$ The copper-catalysed reaction of 2-phenyloxetane 173 with methyl diazoacetate 174 afforded a mixture of the cis and trans-tetrahydrofuran 175.

Scheme 36

This [1,2]-shift cannot operate through a concerted process because this would contravene the Woodward-Hoffmann rules. ${ }^{60} \mathrm{~A}$ free oxonium ylide rearranges via a homolysis-recombination mechanism (Scheme 37), established on the basis of CIDNP NMR data, consistent with an oxonium ylide intermediate undergoing homolytic cleavage to produce a singlet radical pair, followed by cage recombination. ${ }^{61}$

Scheme 37

West and co-workers investigated the formation of tetrahydrofuranones and tetradropyranones using the tandem oxonium ylide formation [1,2]-shift protocol (Scheme 38). ${ }^{62}$ The tetrahydrofuranones 178 were obtained in relatively good yields (eq 1). However, it was noticed that the C-H insertion reaction was competitive to the oxonium ylide formation, when there was a choice between formation of a five-membered ring via insertion and formation of a sixmembered cyclic oxonium ylide (eq 2). This resulted in formation of cyclopentanone 181 in higher yield than the tetrahydropyranone 180.

Scheme 38

West and co-workers then studied the synthesis of bridged bicyclic ethers (Scheme 39). ${ }^{63}$ All their substrates displayed complete group selectivity, meaning that the carbon atom bearing the best radical stabilising substituent migrated preferentially. Both compound 182 and 183 promoted efficient
[1,2]-Stevens shift affording the bicyclic ethers 184 and 185 as a diastereoisomeric mixture. In each case, the major diastereomer was the one in which there was retention of configuration. The cis-compound 182 showed higher retention of configuration, whereas the substrate 183 afforded the bicyclic products in higher yield.

Scheme 39

### 1.4.2 The [2,3]-Sigmatropic Rearrangement

Intramolecular oxonium ylide formation and subsequent [2,3]-sigmatropic rearrangement was developed and reported independently by Pirrung and Werner ${ }^{64}$ as well as Roskamp and Johnson ${ }^{65}$ in 1986. The intramolecular reaction of an allylic ether with an $a$-diazoketone catalysed by rhodium(II) acetate formed a cyclic allylic oxonium ylide that readily underwent [2,3]-sigmatropic rearrangement to deliver five-, six- and eight-membered cyclic ethers (Scheme 40). Furanones were obtained in good yields, apart from the alkenecontaining compound 190 which proved to be unstable. Six-membered rings 196 and 197 were formed in lower yields due to C-H insertion, which competed affectively with oxonium ylide formation. The formation of eight-membered bicyclic ethers 193 and 194 via a three-carbon ring expansion is particularly noteworthy as eight-membered ethers are a common feature of several natural products.

Scheme 40

Intermolecular formation of oxonium ylides from allylic ethers can result in poor yields due to the competing cyclopropanation reaction. The ratio between cyclopropanation and ylide formation is dependent of the steric environment of both, the ether oxygen and the alkene, as well as the nature of the catalyst used. In some cases, good selectivities for the oxonium ylide formation and subsequent [2,3]-sigmatropic rearrangement can be obtained. Following the successful development of the intramolecular protocol, Doyle and co-workers developed an intermolecular version of this tandem procedure. ${ }^{66}$ Oxonium ylide 200 was obtained almost exclusively when diazoketone 198 and allylic methyl ether 199 were treated with rhodium(II) acetate dimer (Scheme 41). Rearrangement of the putative oxonium ylide was thought to proceed via an envelope transition state where the 0 -methyl and the ketone group were in a trans position in order to minimise steric interactions. The geometry of the alkene starting material dictated the relative stereochemistry of the product.

$$
\begin{aligned}
& R^{1}=P h, R^{2}=P h, R^{3}=H, 80 \%, 201: 202,91: 1 \\
& R^{1}=P h, R^{2}=H, \quad R^{3}=P h, 64 \%, \text { 201:202, 19:81 }
\end{aligned}
$$

Scheme 41

Clark studied the diastereochemical outcome of the intramolecular reaction to give dihydrofuranones (Scheme 42). ${ }^{67}$ Treatment of the diazoketone 203 with a copper or rhodium catalyst delivered the tetrahydrofurans 204 and 205. The ratios in which the cis or trans products were obtained varied, depending on the catalyst used. This suggested that the rearrangement was occurring via a metalbound ylide (path a), or that ylide formation was selective for one of the diastereotopic lone pair of electrons of the oxygen leading to 208 (path b). In order to obtain stereocontrol with path $b$, the rearrangement rate needs to be greater than the rate of inversion at the oxonium centre which seems unlikely.

203

$$
\begin{array}{ll}
\mathrm{Rh}_{2}(\mathrm{OAc})_{4} \\
\mathrm{Cu}(\mathrm{acac})_{2}, \text {, THF } & 51 \% \text {, 204:205 65:35 } \\
\text { 83\%, 204:205 97:3 }
\end{array}
$$

203

208
Scheme 42

Clark and co-workers also explored the challenging synthesis of six-, seven- and eight-membered rings known to be difficult to obtain due to the competing $\mathrm{C}-\mathrm{H}$ insertion reactions (Scheme 43). ${ }^{68}$ Once again the catalyst as well as the solvent system proved to have a dramatic influence on the formation of the desired product. Copper appeared to be the metal of choice, favouring oxonium ylide formation over C-H insertion. The six- and seven-membered cyclic ethers 210 and 213 were obtained in good yield, and the oxocan-3-one 216 was formed in moderate yield. The role of the catalyst for these reactions was unclear but it appeared that increasing the electron demand of the catalyst ligands promoted the reaction. It was thought that the high yield obtained when $\mathrm{Cu}(\mathrm{hfacac})_{2}$ was used as catalyst resulted from the stabilisation of the metal-bound ylide intermediate. This would either suppress reformation of the original carbenoid species or would reduce the energy difference between the metal-bound ylide-species and the transition state of the rearrangement reaction.

Some years later West and co-workers developed an iterative method for the synthesis of polycyclic ether natural products (Scheme 44). ${ }^{69}$ Under optimised conditions, diazoketone 217 underwent oxonium ylide formation and subsequent [2,3]-sigmatropic rearrangement in good yield giving a mixture of the rearrangement products 218, 219 and the C-H insertion product 220. A two step procedure gave the desired cis product 221 from the mixture of diastereomers 218 and 219. Alcohol 221 was readily transformed into the diazoketone 222 in three steps. Copper-catalysed oxonium ylide formation and [2,3]-sigmatropic rearrangement then delivered the tricyclic ether 223 in good yield as the only diastereomer.

a) $\mathrm{Cu}(\text { tfacac })_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, reflux, $80 \%$, 218:219:220, 1:30:2; b) i) DBU ; ii) $\mathrm{LiAlH}_{4}, 86 \%$ (TPAP/NMO recycling 88\%); c) $\mathrm{O}_{3}, \mathrm{H}_{2} \mathrm{O}_{2}, \mathrm{HCO}_{2} \mathrm{H}$; d) $\mathrm{KH}, \mathrm{DME}, \mathrm{CH}_{2} \mathrm{CHCH}_{2} \mathrm{Br}, 67 \%$ (2 steps); e) $i$-BuOCOCl, $\mathrm{CH}_{2} \mathrm{~N}_{2}, 44 \%$; f) $\mathrm{Cu}(\text { (ffacac })_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, reflux, $80 \%$.

## Scheme 44

Recently Hodgson and co-workers reported one-pot alkene cross-metathesis, oxonium ylide formation and highly diastereoselective [2,3]-sigmatropic rearrangement for the synthesis of hyperolactone C , an anti-HIV agent (Scheme 45). ${ }^{70}$ The one-pot procedure was first explored using model systems, resulting in good yield and diastereoselectivity in favour of the syn product 227 obtained from the endo transition state 225.

Scheme 45

Hyperolactone C was obtained in five steps from the diazoketone 229 (Scheme 46). Cross-metathesis with methacrolein formed the enone 230, which underwent oxonium ylide formation and subsequent [2,3]-sigmatropic
rearangement. Reduction of 231 gave hemiketal 232 in $26 \%$ yield over 3 steps. Spirolactonisation of the hemiketal 232 using DBU was followed by dehydrogenation to afford hyperolactone C .

Scheme 46

### 1.4.3 The [1,4]-Shift

In general, oxonium ylides can undergo two major transformations, the [1,2]-Stevens shift or the [2,3]-sigmatropic rearrangement. A less common oxonium ylide transformation is the [1,4]-shift reaction. Products from this reaction were first detected by Pirrung and co-workers in rhodium(II)-mediated reactions. ${ }^{71}$ Products resulting from [1,4]-shift reactions have also been isolated in low yield by West ${ }^{72}$ and Clark ${ }^{73}$ from copper(II)-catalysed reactions. Treatment of diazoketone 233 with copper(II) gave a mixture of three products (Scheme 47). The major product 234 was the [1,2]-Stevens shift product, whereas the C-H insertion product 236 was obtained in a very small amount. Compound 235 resulting from the [1,4]-shift was obtained in a surprisingly high $24 \%$ yield. ${ }^{72}$ West proposed a mechanism for the formation of the [1,2]- and [1,4]-products. It was assumed that the [1,4]-product was formed from the radical pair intermediate 239 (path a) that led to recombination at the oxygen rather than at the carbon for the [1,2]-shift. However the radical homodimer
was never isolated and so an alternative metal-assisted mechanism was proposed (path b).

Scheme 47

Dhavale and co-workers observed that rhodium catalysed decomposition of $a$-diazo $B$-keto esters afforded high yields of [1,4]-shift product 245 (Scheme 48). ${ }^{74}$ Competitive studies on the $[1,4]$-shift versus the [1,2]-shift showed that in general the increase in electron density on the benzylic carbon of the migratory group resulted in the preferential [1,4]-migration pathway, while a decrease in the electron density led to a predominance of the [1,2] product. Dhavale proposed an independent mechanistic pathway for the rhodiumcatalysed formation of [1,4]-migrated product. This mechanism involved the formation of metal-bound oxonium ylides 247 and 248. However, 248 would be unproductive for the $[1,4]$-shift due to the large distance between the migration origin and its terminus. Instead, the reaction would proceed via the migration of the benzylic group from oxygen to rhodium. 250 would be the common intermediate in both the [1,2]- and [1,4]-shift pathways.

### 1.4.4 Clark Group Approach Towards Natural Product Synthesis via Diazo Carbonyl Chemistry

Following the successful synthesis of five-, six- and seven-membered cyclic ethers presented earlier (Scheme 43, 44), Clark and co-workers embarked on the synthesis of a small natural product using the [2,3]-sigmatropic rearrangement of oxonium ylide as a key step, decarestrictine $L$ was synthesised in both racemic ${ }^{75}$ and enantiopure ${ }^{76}$ form (Scheme 49). Diazoketone 254 was obtained in 5 steps from the chiral starting material 253. Tetrahydropyran 255 was formed in good yield and with high diastereomeric excess in favour of the trans-product, using $\mathrm{Cu}(\mathrm{hfacac})_{2}$ as catalyst.

Scheme 49

Clark and co-workers have also demonstrated that the catalyst has a great influence on the diastereomeric outcome in the synthesis of tetrahydrofurans via [2,3]-sigmatropic rearrangement (Scheme 42). This methodology was used for the synthesis of the A-ring fragment of the gambieric acids (Scheme 50). ${ }^{77}$ Diazoketone 257 underwent smooth tandem oxonium ylide formation and [2,3]-sigmatropic rearrangement to afford tetrahydrofuran 258 in good yield. The use of $\mathrm{Cu}(\mathrm{acac})_{2}$ enables products possessing the trans configuration to be obtained with high diastereomeric excess. Further functionalisation of the trans-dihydrofuranone 258 afforded the A-ring fragment of the gambieric acids.

A-ring fragement of the gambieric acids

256

Scheme 50

Metal carbenoid reactions have also been used for the synthesis of the core ring systems of complex terpenoids such as neoliacinic acid (Scheme 51). ${ }^{78}$ The synthetic route involved two metal carbenoid transformations. First diazoketone 259 was treated with $\mathrm{Rh}_{2}$ (tfacam) $)_{4}$ to promote $\mathrm{C}-\mathrm{H}$ insertion, producing cis-tetrahydrofuran 260. A few steps were required for the preparation of the second metal carbenoid precursor diazoketone 261. This time copper(II) was
used to catalyse oxonium ylide formation and subsequent [2,3]-sigmatropic rearrangement, delivering the bridged bicyclic ether 262 in $69 \%$ yield as a 3:2 mixture of $Z$ - and $E$-isomers. Further transformations afforded the late stage intermediate lactone 263. Studies towards the total synthesis of neoliacinic acid are ongoing in the Clark group.

Scheme 51

The tricyclic core of the cladiellin labiatin $A,{ }^{79}$ was synthesised using a similar approach (Scheme 52). Rhodium(II) catalysed C-H insertion of diazoketone 264 afforded tetrahydrofuran 265 in $66 \%$ yield as $7: 1$ cis:trans ratio. Diazoketone 266 was prepared in a few steps from 265, before treatment with a copper(II)catalyst induced oxonium ylide generation. The [2,3]-sigmatropic rearrangement with the cyclic alkene afforded, diastereoselectively, the tricyclic core 267 of labiatin A in $76 \%$ yield. Further transformations afforded the late stage epoxide 268. Work is ongoing in the Clark group towards the completion of the synthesis of labiatin A.

Scheme 52

### 1.5 Retrosynthetic Analysis

Following the success of the total synthesis of vigulariol, other members of the cladiellin family were identified as targets. First, the synthesis of a cladiellin bearing a Z-alkene within the medium-sized ring was designed. Our retrosynthetic analysis of ophirin B is shown in Scheme 53. Epoxide formation gives the compound 269. Replacement of the methylene group with a carbonyl group, and removal of the epoxide affords the enone 270 . Reduction of the alkene, conversion of the carbonyl group into an enol ether gives diol 271. Removal of the C-3 (cladiellin numbering) methyl group and Grignard disconnection of the hydroxypropyl group to give a methyl ketone afford the key intermediate 272. The synthesis of an intermediate corresponding to synthon 272 had already been reported during the synthesis of the vigulariol. A DielsAlder disconnection gives the bridged bicyclic diene 273 and methyl vinyl ketone. Conversion of the diene into a carbonyl group leads to the bicyclic ketone 274 which can be obtained from the diazo ketone 275 . Removal of the diazo group gives the tetrahydropyranyl ester which leads to the aldehyde 276
by ring-opening. Further disconnection gives the allylic alcohol 277 as the starting material.

Scheme 53

The tandem oxonium ylide formation [2,3]-sigmatropic rearrangement of diazoketone 275 (Scheme 54) is the key step of our synthetic route. Studies toward the selective formation of E-bicyclic ketone 278 will be undertaken in order to construct cladiellins possessing an $E$-alkene embedded in the mediumsized ring.

Scheme 54

Cladiella-6,11-dien-3-ol was selected as our initial E-cladiellin target because Kim and co-workers had already shown that it can easily be transformed into more complex natural products. ${ }^{31}$ Once again, we aimed to use the strategy developed for the synthesis of the vigulariol to obtain this product (Scheme 55). Removal of the C-3 (cladiellin numbering) methyl group gives 279. Ketone formation and oxidation of the isopropyl group affords the alkene 280. Conversion of the carbonyl group into an enol ether, and of the methylene into a methyl ketone gives 281. Diels-Alder disconnection affords the bicyclic diene 282 and methyl vinyl ketone. Transformation of the diene unit into a carbonyl group gives the bicyclic ketone 278. This ketone can be obtained from diazo ketone 275 an intermediate common to the synthesis of vigulariol and ophirin B.

Scheme 55

## 2 Results and Discussion

### 2.1 Introduction

Following the successful total synthesis of vigulariol, the synthesis of other members of the cladiellin family was proposed (Scheme 56). The first challenge was the development of an efficient enantioselective synthesis of the allylic alcohol 284, a common intermediate in the synthesis of all our targets. Indeed, our proposed synthetic route was highly diastereoselective and the single stereocentre in 284 would control all the other stereocentres introduced during the synthesis. Our next challenge was to develop conditions for the oxonium ylide formation and subsequent [2,3]-sigmatropic rearrangement giving E-bicyclic ketone 72 in good yield and selectivity. The tricyclic core of the Z-cladiellins was already accessible using the route developed for the synthesis of vigulariol. The completion of the total synthesis of ophirin B would require functionalisation of the tricyclic core. The formation of the $E$-cladiellin core and its functionalisation was the aim of the second part of the project.

## 2．2 Synthesis of the Bicyclic Ketones Intermediates 72 and 73

## 2．2．1 Synthesis of the Allylic Alcohol Precursor 284

Racemic allylic alcohol（土）－284 was easily obtained in two steps（Scheme 57）． First，protection of commercially available 3－bromopropan－1－ol 285 gave the TBS silyl ether 67．Subsequent treatment with magnesium afforded the corresponding Grignard reagent，which was reacted with methacrolein to produce allylic alcohol（土）－284．The yield of this reaction was dependent on the number of equivalents of the Grignard reagent used．Optimised conditions required 2 equivalents of bromide 67 relative to methacrolein，and gave（土）－284 in excellent $93 \%$ yield．

a） $\mathrm{TBSCI}, \mathrm{DMAP}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 86 \%$ ；b）i） $\mathrm{Mg}, \mathrm{I}_{2}$ ，THF，ii）methacrolein，THF，rt， $93 \%$ ．
Scheme 57

Previous work in the Clark group has shown that the enantiopure allylic alcohol （＋）－284 could be obtained with $96 \%$ ee using the Corey－Bakshi－Shibata（CBS） reduction of the corresponding enone（Scheme 58）．${ }^{80,}{ }^{81}$ Manganese（IV）oxide oxidation of allylic alcohol（土）－284 formed enone 286 in 78\％yield，which was reduced using CBS－oxazaborolidine 287 to afford the allylic alcohol（＋）－284 in $86 \%$ yield．Good enantiomeric excesses were only obtained when 1.2 equivalents of high purity oxazaborolidine were used．Although this method delivered the allylic alcohol（＋）－284 with high selectivity，the fact that substantial quantities of a chiral reagent were required made this route too expensive to be used for the formation of very large quantities of the synthesis precursor．

Scheme 58

The search for an efficient, scalable and affordable route to the enantiopure allylic alcohol (+)-284 started with the synthesis of the esters 290 and 291 (Scheme 59). It was thought that taking advantage of our industrial sponsor's supercritical fluid chromatography (SFC), the two enantiomers of esters 290 and 291 could be separated. It was hoped that the enantiopure esters would be crystalline, and that co-crystallisation with the racemic product would afford large quantities of enantiopure product. However, despite many attempts by the Merck's SFC specialist, esters 290 and 291 enantiomers could not be separated.

a) $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt, (288, 63\%); (289, 17\%); b) SFC separation.

Scheme 59

We then considered the kinetic resolution of racemic allylic alcohol (土)-284. First, the well established Sharpless kinetic resolution method was investigated. ${ }^{82}$ This method, relies on the difference in reactivity towards epoxidation of the two enantiomers of a racemic allylic alcohol in the presence of a chiral tartrate. Sharpless and co-workers reported the kinetic resolution of 292, a substrate similar to ours (Scheme 60, eq. 1). The $R$-enantiomer of allylic alcohol ( $R$ )-292 was obtained in $96 \%$ ee when ( $\mathbf{\pm}$ )-292 was treated with (+)-diisopropyltartrate, titanium isopropoxide and tert-butyl hydroperoxide. More recently, Fujiwara and co-workers have used the Sharpless kinetic resolution on an almost identical substrate to ours ( $\pm$ )-294 during their formal
synthesis of hemibrevetoxin B (eq. 2). ${ }^{83}$ This time the (-)-diisopropyltartrate was used, delivering the S-allylic alcohol (S)-294 in 97\% ee.

$30-45 \%$; $96 \%$ ee

Scheme 60

The same conditions were applied to our substrate ( $\pm$ )-284 (Scheme 61). $(+)$-Diisopropyl tartrate was used in order to obtain $R$-allylic alcohol (+)-284. The reaction was followed by NMR and quenched when it reached $60 \%$ conversion. On small scale ( 250 mg ) the reaction afforded $41 \%$ yield of epoxy alcohol 296, and the unreacted $R$-allylic alcohol (+)-284 was recovered in $36 \%$ yield. The enantiomeric purity was assayed by normal phase chiral HPLC analysis ${ }^{84}$ of the corresponding vinylogous carbonate (-)-297, obtained by treatment of (+)-284 with ethyl propiolate and $N$-methylmorpholine. In this case material with an $86 \%$ enantiomeric excess was obtained. However, on larger scale ( 5 g ) the reaction failed to deliver any epoxy alcohol 296. This was explained by the fact that as reported by Sharpless, the reaction was carried out without stirring in the freezer at $-20{ }^{\circ} \mathrm{C} .{ }^{82 \mathrm{~b}}$ On large scale, the lack of stirring seemed to have a great impact on the reactivity.

( $\pm$ )-284

(+)-284

94\%

(+)-284
$36 \%$; $86 \%$ ee

OTBS

(-)-297

The second kinetic resolution protocol considered was developed by Fu and co-workers. ${ }^{85}$ In this protocol a planar-chiral DMAP derivative 300 was used as an efficient catalyst for the kinetic resolution of racemic allylic alcohols via acetylation (Scheme 62). Fu and co-workers reported the kinetic resolution of allylic alcohol (土)-298, a similar substrate to ours, affording ( $R$ )-298 with $93 \%$ ee. One of the advantages of this method is that the unwanted enantiomer is acetylated. In our case after separation of acetate 301 from unreacted allylic alcohol (+)-284, the ester should easily be cleaved revealing the unwanted enantiomer (-)-284 of the allylic alcohol. Mitsunobu protocol would then be used to invert the configuration delivering more allylic alcohol (+)-284. However, applying Fu's conditions to our substrate afforded allylic alcohol (+)-284 in $36 \%$ yield and with only $83 \%$ ee. Moreover, the drawback of this technique was the very slow reaction rate. On a small scale ( 120 mg ) the reaction needed 12 days to reach the $60 \%$ of conversion needed. The slow reaction rate made this technique unsuitable for large scale synthesis of our enantiopure precursor (+)-284.

Scheme 62

Due to the poor results obtained with various kinetic resolution procedures another approach was considered. Williams and co-workers have reported the four-step synthesis of allylic alcohol (+)-284 from 4-(tertbutyldimethylsilyloxy)butanal 304 in $61 \%$ overall yield and $97 \%$ ee. ${ }^{86}$ This synthesis featured the introduction of the stereogenic centre in a highly enantioselective manner by Sharpless asymmetric epoxidation of an allylic alcohol. Repetition of the published synthesis had been attempted by a previous member of the Clark group. However, as no experimental procedures were available in the original paper, ${ }^{86}$ the six-step synthesis of the allylic alcohol (+)-284 from butandiol was performed in only $35 \%$ overall yield and gave the product with $85 \%$ ee. ${ }^{80}$ Nevertheless, we thought that optimisation of the reaction conditions could afford the allylic alcohol (+)-284 in both higher yield and enantiomeric excess.

Butandiol 302 was mono-protected, delivering the TBS ether 303 in $90 \%$ yield (Scheme 63). The remaining primary alcohol of 303 was oxidised using Swern conditions and the newly formed aldehyde 304 was immediately used in a Wittig olefination reaction with commercially available (carbethoxyethylidene) triphenylphosphorane delivering the $a, B$-unsaturated ester 305 in $95 \%$ yield over two steps. For large scale synthesis the phosphorane was readily prepared from ethyl-2-bromopropionate and triphenylphosphine. ${ }^{87}$

a) $\mathrm{TBSCI}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 90 \%$; b) $(\mathrm{COCl})_{2}, \mathrm{DMSO}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-78{ }^{\circ} \mathrm{C}$; c) $\mathrm{Ph}_{3} \mathrm{PC}\left(\mathrm{CH}_{3}\right) \mathrm{COOEt}$, THF, rt, 95\% (2 steps).

Scheme 63

Following formation of the $a, B$-unsaturated ester 305 in very good yield, synthesis of the Sharpless epoxidation precursor, allylic alcohol 306, and its
subsequent epoxidation was investigated. The highest yield for the reduction of the ester 305 was obtained when the reaction was kept at $-78{ }^{\circ} \mathrm{C}$ and only 2.5 equivalents of DIBAL-H were used (Table 3, entry 2 ).

| Entry | Conditions | Yield |
| :---: | :---: | :---: |
| 1 | 3.0 eq DIBAL-H ( 1 M in hexane), $-78{ }^{\circ} \mathrm{C}$ to $0{ }^{\circ} \mathrm{C}$ | $31 \%$ |
| 2 | 2.5 eq DIBAL-H (1M in hexane), $-78{ }^{\circ} \mathrm{C}$ | $94 \%$ |

Table 3

Various conditions were explored for the Sharpless enantioselective epoxidation (Table 4). Epoxide (+)-307 was obtained in higher yield and ee when each reagent was used in low loading (entry 2). In order to determine the enantiomeric excess obtained with the different Sharpless conditions, the synthesis was continued up to the formation of the corresponding vinylogous carbonates (-)-297 (Scheme 61). The carbonates (-)-297 were then assayed as previously by normal phase chiral HPLC analysis. ${ }^{84}$

|  |  |  |  |
| :---: | :---: | :---: | :---: |
| Entry | Conditions | Yield | ee |
| $1^{88}$ | $20 \mathrm{~mol} \%(-)-\mathrm{DET}, 15 \mathrm{~mol} \% \mathrm{Ti}(\mathrm{OiPr})_{4}$, 2 eq TBHP ( 5.6 M in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ), $4 \AA \mathrm{MS},-20^{\circ} \mathrm{C}$ | 64\% | 93\% |
| $2^{82 b, 89}$ | $7.5 \mathrm{~mol} \%(-)-\mathrm{DET}, 5 \mathrm{~mol} \% \mathrm{Ti}(\mathrm{OiPr})_{4}$, 1.5 eq TBHP ( 5.6 M in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ), $4 \AA \mathrm{MS},-20^{\circ} \mathrm{C}$ | 95\% | 94\% |

## Table 4

Epoxy alcohol (+)-307 was then converted into the enantio-enriched allylic alcohol (+)-284 (Scheme 64). Mesylation of the primary alcohol (+)-307
afforded the corresponding epoxy mesylate 308 which was immediately treated with sodium iodide to form the epoxy iodide 309 in situ. Addition of zinc powder formed an organometallic intermediate and opening of the epoxide delivered the corresponding allylic alcohol (+)-284 in 97\% yield.

a) i) $\mathrm{MsCl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$; ii) $\mathrm{NaI}, \mathrm{Zn}$, butan-2-one, $80^{\circ} \mathrm{C}, 97 \%$.

Scheme 64

These optimised conditions gave access to enantioenriched allylic alcohol (+)-284 with $94 \%$ ee and in sufficient quantities to continue the enantioselective synthesis of our target. All the chemicals used for the synthesis of (+)-284 were affordable in large quantities. The scale-up of the synthesis was performed without problem in batches of 30 g delivering 90 g of allylic alcohol (+)-284 with 94\% ee and in 74\% yield over the six steps.

In order to define a viable route for the synthesis of our natural product targets, primary work was carried out using racemic material. Most of the reactions were optimised using only racemic material. This will be emphasised in the following parts of this thesis by the ( $\pm$ ) symbol before the molecule number. The enantioselective synthesis was then accomplished using the optimised synthetic route, all compounds prepared as single enantiomers will have their number preceded by the sign of their optical rotation.

### 2.2.2 Synthesis of the diazoketone 70

With allylic alcohol precursor (+)-284 now available on large scale in both racemic and enantiopure form, the synthesis of diazoketone (+)-70 was undertaken using the route developed for the synthesis of vigulariol. Allylic alcohol (+)-284 was first alkylated with ethyl propiolate to produce the corresponding $E$-vinylogous carbonate (-)-297 in 94\% yield (Scheme 65). ${ }^{90}$ Then
acidic cleavage of the silyl ether protecting group revealed primary alcohol (-)-310.

a) ethyl propiolate, $\mathrm{NMM}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt, $94 \%$; b) $\mathrm{CSA}, \mathrm{MeOH}, ~ r t, 86 \%$.

Scheme 65

Primary alcohol (-)-310 was oxidised using Swern conditions to afford aldehyde (-)-68 in 97\% yield (Scheme 66). Then reductive cyclisation was realised using the conditions developed by Nakata and co-workers. ${ }^{44,91}$ Treatment of aldehyde (-)-68 with freshly prepared $\mathrm{Sml}_{2}$ and methanol afforded the tetrahydropyranol (+)-69 in 86\% yield. As previously reported, the tetrahydropyranol exhibited a 2,3 trans geometry confirmed by the large 9.2 Hz coupling constant between H-2 and $\mathrm{H}-3$.

a) $(\mathrm{COCl})_{2}, \mathrm{DMSO}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-78^{\circ} \mathrm{C}, 97 \%$; b) $\mathrm{Sml}_{2}, \mathrm{MeOH}, \mathrm{THF}, \mathrm{rt}, 86 \%$.

Scheme 66

Tetrahydropyranol (+)-69 was protected as a TBS ether in $96 \%$ yield before lithium hydroxide mediated saponification formed carboxylic acid (+)-312 in 89\% yield (Scheme 67). Diazoketone formation was achieved via activation of the carboxylic acid as a mixed anhydride. Treatment of carboxylic acid (+)-312 with isobutylchloroformate formed the mixed anhydride, which was added directly to a freshly prepared ethereal solution of diazomethane. A large excess (10 eq) of diazomethane was needed in order to obtain high yields. Batches of 100 mmol of
diazomethane were prepared from $N$-methyl- $N$-nitroso- $p$-toluenesulfonamide (Diazald ${ }^{\circledR}$ ) using macro Diazald apparatus. ${ }^{92}$

a) TBSCl , imidazole, DMF , rt, $96 \%$; b) $\mathrm{LiOH}, \mathrm{EtOH}: \mathrm{H}_{2} \mathrm{O} 3: 1$, rt, $89 \%$; c) i) $i-\mathrm{BuO}_{2} \mathrm{CCl}$, $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{Et}_{2} \mathrm{O}$, rt; ii) $\mathrm{CH}_{2} \mathrm{~N}_{2}, \mathrm{Et}_{2} \mathrm{O}, \mathrm{O}^{\circ} \mathrm{C} \rightarrow \mathrm{rt}, 88 \%$.

Scheme 67

### 2.2.3 Studies on the Tandem Oxonium Ylide Formation and [2,3]Sigmatropic Rearrangement

Diazoketone (+)-70 is an important intermediate in our synthesis. It is the precursor of our key transformation: the oxonium ylide formation and subsequent [2,3]-sigmatropic rearrangement, and the point of divergence of the synthetic routes to the $E$ - and $Z$-cladiellin natural product series.

Previous work has shown that treatment of diazoketone (+)-70 with copper(II) hexafluoroacetylacetonate in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at reflux delivered in $95 \%$ yield a mixture of bicyclic ketones (+)-73 and (-)-72 in a 5:1 ratio (Scheme 68). These two bicyclic ketones were separable using silica gel impregnated with $10 \%$ silver nitrate. ${ }^{93}$ Moreover, the strained $E$-isomer (-)-72 could be isomerised to the less strained Z-compound (+)-73 using ethanethiol and AIBN. This technique allowed an efficient synthesis of Z-bicyclic ketone (+)-73 used in the synthesis of Z-cladiellins such as vigulariol and ophirin B.

a) $\mathrm{Cu}(\text { hfacac })_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, reflux, $95 \%, Z: E 5: 1$; b) $\mathrm{AIBN}, \mathrm{EtSH}, \mathrm{PhH}$, reflux, $56 \%$.

However, in order to target the synthesis of the E-cladiellin natural products, conditions that delivered E-bicyclic ketone (-)-72 selectively and in higher yields were needed. The oxonium ylide formation and subsequent rearrangement protocol is greatly influenced by the nature of the catalyst used, its ligands as well as the reaction temperature and solvent in which it is performed. Copper catalysts usually favour oxonium ylide formation over C-H insertion. In our case, conditions facilitating the formation of the strained $E$-bicyclic ketone (-)-72 via oxonium ylide formation and subsequent [2,3]-sigmatropic rearrangement from diazoketone (+)-70 were required.

Previous work in the Clark group has shown that $\mathrm{Cu}(\mathrm{hfacac})_{2}$ was the metal of choice for the oxonium ylide formation and subsequent [2,3]-sigmatropic rearrangement from diazoketone (+)-70. It was also known that the solvent in which the reaction was performed had an influence on both the yield and the ratio of compounds (-)-72 and (+)-73 obtained (Table 5). ${ }^{80}$ However no correlation could be made between the solvent polarity and the yield or product distribution of the reaction. Performing the reaction in refluxing THF (Table 5, entry 3) gave a higher proportion of the Z-bicyclic ketone (+)-73 in a lower yield (74\%) compared to that obtained when the reaction was performed in refluxing dichloromethane. All the solvents previously tested for the $\mathrm{Cu}(\mathrm{hfacac})_{2}$ catalysed reaction gave preferentially the Z-isomer (+)-73 in ratios ranging from 3.1:1 up to 6.9:1 and in good yield (entries 1 to 7 ). Temperature had little effect on the yield or the product distribution when dichloromethane was used as solvent, but increasing the temperature allowed a shorter reaction time (Table 5, entries 1, 6, 7). Finally, it was observed that switching from a copper to a rhodium catalyst resulted in a drop in yield to 52\% (entry 8) and gave a nearly equimolar amount of bicyclic products (-)-72 and (+)-73.

| Entry | Catalyst | Solvent | Temperature | Duration | Ratio Z:E | Yield |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{Cu}(\text { hfacac })_{2}$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | reflux | 15 min | $5.0: 1$ | $95 \%$ |
| 2 | $\mathrm{Cu}(\text { hfacac })_{2}$ | DCE | reflux | 15 min | $3.9: 1$ | $85 \%$ |
| 3 | $\mathrm{Cu}(\text { hfacac })_{2}$ | THF | reflux | 45 min | $6.9: 1$ | $74 \%$ |
| 4 | $\mathrm{Cu}(\text { hfacac })_{2}$ | $\mathrm{Et}_{2} \mathrm{O}$ | reflux | 15 min | $3.1: 1$ | $93 \%$ |
| 5 | $\mathrm{Cu}(\text { hfacac })_{2}$ | benzene | reflux | 30 min | $4.8: 1$ | $94 \%$ |
| 6 | $\mathrm{Cu}(\text { hfacac })_{2}$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | rt | 3 h | $5.9: 1$ | $94 \%$ |
| 7 | $\mathrm{Cu}(\text { hfacac })_{2}$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | $0{ }^{\circ} \mathrm{C}$ | 7 h | $5.5: 1$ | $96 \%$ |
| 8 | $\mathrm{Rh}_{2}(\mathrm{OAC})_{4}$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | reflux | 1 h | $1.2: 1$ | $52 \%$ |

Table $5^{80}$

In the light of these preliminary results, it was decided to screen more polar solvent systems for $\mathrm{Cu}(\mathrm{hfacac})_{2}$ catalysed reactions (Table 6). These tests were performed on racemic material in order to save valuable enantiopure material. When using acetonitrile at reflux a nearly equimolar mixture of 72 and 73 was obtained in a poor yield (entry 1). Adding water to the solvent mixture lowered the yield even further (entry 2 ). The use of a 19:1 mixture of acetonitrile:water gave, for the first time, a ratio slightly favouring the $E$-bicyclic ketone 72 (Z:E 1:1.2) in a poor yield (entry 3). The reaction performed in DMF gave a 4.2:1 mixture favouring the Z-bicyclic ketone 73 in poor yield (entry 4). It was then thought that complexing the copper catalyst with pyridine would change its catalytic sphere and this could increase the ratio of the $E$-isomer 72. However, the addition of pyridine to the reaction mixture did not have the desired effect;
bicyclic ketone 72 and 73 were obtained in good yield but the Z-product 72 was obtained preferentially (entries 5 and 6).

| Entry | Catalyst ${ }^{\text {a }}$ | Solvent | Temperature | Duration | $\begin{aligned} & \text { Ratio } \\ & Z: E^{b} \end{aligned}$ | Yield ${ }^{\text {c }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{Cu}(\mathrm{hfacac})_{2}$ | MeCN | reflux | 1 h | 1.2:1 | 27\% |
| 2 | $\mathrm{Cu}(\mathrm{hfacac})_{2}$ | $\begin{gathered} \mathrm{MeCN}: \mathrm{H}_{2} \mathrm{O} \\ 9: 1 \end{gathered}$ | reflux | 1 h | 2.6:1 | 9\% |
| 3 | $\mathrm{Cu}(\mathrm{hfacac})_{2}$ | $\begin{gathered} \mathrm{MeCN}: \mathrm{H}_{2} \mathrm{O} \\ 19: 1 \end{gathered}$ | reflux | 1 h | 1:1.2 | 23\% |
| 4 | $\mathrm{Cu}(\mathrm{hfacac})_{2}$ | DMF | $40{ }^{\circ} \mathrm{C}$ | 1 h | 4.2:1 | 18\% |
| 5 | $\mathrm{Cu}(\mathrm{hfacac})_{2}+$ pyridine (3 mol\%) | DCM | reflux | 20 min | 4.3:1 | 78\% |
| 6 | $\mathrm{Cu}(\text { hfacac })_{2}+$ pyridine (10 mol\%) | DCM | reflux | 40 min | 3.0:1 | 94\% |

Our failure to identify suitable conditions for the copper catalysed synthesis of the $E$-bicyclic ketone 72, led us to expand the scope of our study to include rhodium catalysts. Indeed, preliminary results had shown that refluxing diazoketone 70 and catalytic quantities of rhodium acetate in dichloromethane delivered a nearly equimolar mixture of products 72 and 73 in 52\% yield (Table 5, entry 8). ${ }^{80}$ Moreover, rhodium(II) complexes would provide additional opportunities to tune the reaction to deliver the $E$-isomer 72 , by varying the steric and electronic characteristics of the ligands. Five different rhodium catalysts were screened using dichloromethane at reflux as the standard conditions (Figure 15, Table 7). Rhodium(II) trifluoroacetate $\left[R h_{2}(t f a)_{4}\right]$ gave bicyclic ketones 72 and 73 in a good $90 \%$ yield and a ratio (Z:E 1.7:1) slightly in favour of the Z-isomer (entry 1), while rhodium(II) trifluoroacetamide ${ }^{94}$ $\left[\mathrm{Rh}_{2} \text { (tfacam) }\right)_{4}$ ] gave a ratio which was very slightly in favour of the $E$-bicyclic ketone 72 (Z:E 1:1.2) in $63 \%$ yield (entry 2 ). When the reaction was carried out with rhodium(II) caprolactamate $\left[\mathrm{Rh}_{2}(\mathrm{cap})_{4}\right]$ neither bicyclic ketone 72 nor 73 were obtained (entry 3). More promising results were obtained with rhodium(II)
perfluorobutyrate ${ }^{95}\left[\mathrm{Rh}_{2}(\mathrm{pfm})_{4}\right]$ and rhodium(II) triphenylacetate ${ }^{96}\left[\mathrm{Rh}_{2}(\mathrm{tpa})_{4}\right]$ (entries 4, 5). These catalysts delivered moderate yields of mixtures of products 72 and 73 with $1: 2.7$ and 1:4.3 $Z: E$ ratios in favour of the $E$-isomer.

Figure 15

Table 7

Early results obtained with rhodium(II) perfluorobutyrate and rhodium(II) triphenylacetate were very promising and these two catalysts were selected for further investigation (Table 8). First, the reactions were carried out in dichloromethane at room temperature. This time the temperature at which the reaction was performed had an influence on both the yield and the product distribution. For the two catalysts nearly equal amounts of each isomer were obtained in modest yield (entries 1, 2). Switching the solvent to THF did not improve the $Z: E$ ratio. Using rhodium(II) perfluorobutyrate in THF at reflux gave a relatively good yield (74\%) of the mixture with a $1: 1.7$ Z:E ratio (entry 3 ), but performing the reaction at room temperature considerably decreased the yield
(entry 4). The rhodium(II) triphenylacetate catalysed reaction delivered the same 1:2.7 Z:E ratio when performed in THF at reflux as when carried out in dichloromethane at reflux, but in a lower yield (45\%) (entry 5). The reaction was sluggish and low yielding when performed at room temperature in THF (entry 6). It was noticeable that the best $E$-selectivities were obtained when the reactions were performed at reflux. We decided to test 1,2-dichloroethane (DCE) as solvent as it displays similar solvent properties to dichloromethane but has a higher boiling point. We wanted to determine if increasing the temperature would increase the ratio to favour the $E$ isomer. The use of 1,2 -dichloroethane as a higher boiling point version of dichromethane did not produce the desired effect on the rhodium(II) perfluorobutyrate catalysed reaction (entry 7). It lowered both the yield and the selectivity of the reaction for the formation of the $E$-isomer. However, the highest $E$-selectivity was obtained when rhodium(II) triphenylacetate was used in 1,2-dichloroethane at reflux (entry 8). This gave a 1:6.3 selectivity in favour of the desired E-bicyclic ketone 72 in $56 \%$ yield.

| Entry | Catalyst ${ }^{\text {a }}$ | Solvent | Temperature | Duration | Ratio Z:E ${ }^{\text {b }}$ | Yield ${ }^{\text {c }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{Rh}_{2}(\mathrm{pfm})_{4}$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | rt | 30 min | 1.5:1 | 36\% |
| 2 | $\mathrm{Rh}_{2}(\mathrm{tpa})_{4}$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | rt | 1 h | 1:1.8 | 49\% |
| 3 | $\mathrm{Rh}_{2}(\mathrm{pfm})_{4}$ | THF | reflux | 15 min | 1:1.7 | 74\% |
| 4 | $\mathrm{Rh}_{2}(\mathrm{pfm})_{4}$ | THF | rt | 30 min | 1:1.1 | 19\% |
| 5 | $\mathrm{Rh}_{2}(\mathrm{tpa})_{4}$ | THF | reflux | 15 min | 1:2.7 | 45\% |
| 6 | $\mathrm{Rh}_{2}(\mathrm{tpa})_{4}$ | THF | rt | 18 h | 1.4:1 | 32\% |
| 7 | $\mathrm{Rh}_{2}(\mathrm{pfm})_{4}$ | DCE | reflux | 15 min | 1:1.4 | 66\% |
| 8 | $\mathrm{Rh}_{2}(\mathrm{tpa})_{4}$ | DCE | reflux | 15 min | 1:6.3 | 56\% |

Table 8

The screening of different catalysts, solvents and temperatures has enabled us to identify reaction conditions that favour formation of the $E$-bicyclic ketone 72 which is needed for the synthesis of the E-cladiellins. However, we were not able to correlate the solvent polarity and reaction temperature to the product distribution or the yield of the reaction. The fact that the change in catalyst produced such drastic changes in the reactivity seems to suggest that the
reaction proceeds through a metal bounded ylide intermediate rather than a free ylide. In order to prove that the [2,3]-sigmatropic process was irreversible and that the E-selectivity was not due to product isomerisation, control reactions were carried out (Scheme 69). Each of the bicyclic ketones was heated at reflux in dichloromethane in presence of the catalysts $\mathrm{Cu}(\mathrm{hfacac})_{2}$ or $\mathrm{Rh}_{2}$ (tpa) ${ }_{4}$ for two hours. In all the four cases, the starting material was recovered unchanged, no isomerisation of the double bound was observed. This proved that the [2,3]-sigmatropic rearrangement of the oxonium ylide is an irreversible process and that the rhodium- and copper-catalysts are not able to change the configuration of the double bond after rearrangement has taken place. Given that the [2,3]-sigmatropic rearrangement reaction is irreversible the different isomers observed must arise from different oxonium ylide configurations or from differing transition states.

Scheme 69

In order to explain how the different isomers are formed, we need to look at the various metal carbenoid conformers (Scheme 70). The more stable conformer 313 A has all its substituents in equatorial positions, whereas less stable conformer 313 B has all its substituents in axial positions. From metal carbenoid conformer 313 A the formation of the oxonium ylide should process preferentially via path a, since the reaction with the "axial" lone pair of the oxygen should be easier and form a less strained five-membered ring compared to path c , where the reaction with the equatorial lone pair gives a more strained
five-membered ring. [2,3]-Sigmatropic rearrangement of oxonium ylide 71 A should give the Z-bicyclic ketone 73 whereas [2,3]-sigmatropic rearrangement of oxonium ylide 71 C would form the $E$-bicyclic ketone 72 . The less stable metal carbenoid conformer 313 B should form the oxonium ylide conformer 71 B via path b. Conformer 71 B would then undergo the [2,3]-sigmatropic rearrangement to give the E-bicyclic ketone 72. Ongoing computational calculation of the energy of the different oxonium ylide conformers $71 \mathrm{~A}, \mathrm{~B}, \mathrm{C}$ have shown that the difference in energy between them is rather small, only around $22 \mathrm{kJmol}^{-1} .{ }^{97}$ This means that all conformers should exist in equilibrium and transition states of the [2,3]-sigmatropic rearrangement need to be considered in order to understand the reaction outcome. The results obtained have shown that catalyst, solvent and temperature have a significant influence on the formation of the bicyclic ketones which cannot be explained by this "free" oxonium ylide representation. This finding tends to support the metal-bound ylide intermediate hypothesis.

Scheme 70

### 2.3 Studies Towards the Synthesis of Ophirin B

### 2.3.1 Results

With the Z-bicyclic ketone (+)-73 formed, the synthesis of the tricylic core of the Z-cladiellins was undertaken. As developed in the synthesis of vigulariol, the cladiellin skeleton was built in three steps (Scheme 71). First the enol triflate 314 was formed from ketone (+)-73. It was then used in a Stille cross-coupling with tributyl(1-ethoxyvinyl)tin to deliver the unstable diene 74. ${ }^{98}$ The diene 74 was immediately used in a thermal Diels-Alder cycloaddition with methyl vinyl ketone to yield the tricyclic core of the Z-cladiellin 75 as a $2: 1$ exo:endo mixture. Optimised conditions enabled the formation of tricycle ketone 75 in $69 \%$ yield over three steps. Base-induced epimerisation of the mixture of endo and exo isomers with potassium carbonate provided the more stable exo-product (+)-exo-75, having the methyl ketone group in the equatorial position.

Scheme 71

The Diels-Alder cycloaddition reaction is thought to proceed via transition states 315 and 316 (Figure 16). The cycloaddition reaction proceeded with complete regioselectivity and facial selectivity on the diene component. High regioselectivity resulted from the matched electronics of the electron-rich
alkoxy diene and the electron-deficient dienophile. The diene facial selectivity resulted from the bowl shaped conformation adopted by the molecule blocking the top face of the diene. Cycloaddition was carried out using a large excess of methyl vinyl ketone. As thermal activation was needed and methyl vinyl ketone is volatile, reactions were performed in sealed tubes. Optimisation of the reaction conditions revealed that tricyclic product 75 was obtained in higher yield when the reaction was executed at relatively low concentration ( $0.025 \mathrm{molL}^{-1}$ ). In cases were higher concentrations were used, uncharacterised sides products were obtained leading to a decrease in the yield of the reaction.

Figure 16

Tricyclic ketone (+)-exo-75 corresponds to the point of divergence between the synthesis of vigulariol and the route towards ophirin B. With the tricylic skeleton of the cladiellin formed all that remained was functional group manipulations around the molecule. Our first goal was to form the two tertiary alcohols present on ophirin B as tertiary acetates. Initially, the ketone was methylated to deliver the first tertiary alcohol (+)-317 (Scheme 72). Various alkylation reagents were tested and the best yield was obtained by Grignard addition of methyl magnesium chloride. Cleavage of the TBS ether proceeded smoothly revealing the diol (+)-271 in 91\% yield.

a) MeLi, THF, $-78^{\circ} \mathrm{C}, 47 \%$; b) $\mathrm{MeMgCl}, \mathrm{THF}, 0^{\circ} \mathrm{C} \rightarrow \mathrm{rt}, 84 \%$; c) TBAF, $4 \AA \mathrm{MS}$, THF, rt, 91\%.

Scheme 72

Secondary alcohol ( $\pm$ )-271 was then oxidised to form the cyclic ketone ( $\pm$ )-319. Different oxidation procedures were tested, but unfortunately all of them afforded the ketone ( $\pm$ )-319 in poor yield due to its instability (Table 9).

| Method | Conditions | Outcome / Yield |
| :---: | :---: | :---: |
| Swern $^{99}$ | $(\mathrm{COCl})_{2}$, DMSO, $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2},-78{ }^{\circ} \mathrm{C}$ | Decomposition |
| Parikh-Doering ${ }^{100}$ | $\mathrm{SO}_{3}$ pyridine complex, DMSO, DIPEA, | $56 \% ; 92 \%$ brsm |
| CHe $_{2} \mathrm{Cl}_{2}, 0{ }^{\circ} \mathrm{C}$ |  |  |
| Dess-Martin |  |  |

Table 9

In order to avoid decomposition of ketone 319 the decision was taken to use the crude material directly in the next step (Scheme 73). Dess-Martin oxidation immediately followed by Grignard addition with methyl magnesium chloride afforded the diol (+)-320 in 54\% over two steps. The successful use of methyl lithium in presence of sodium tetrafluoroborate for the introduction of the C-3 methyl group had been reported by Paquette ${ }^{23}$ and $\mathrm{Kim}^{31}$ on similar cladiellin systems. However, in our case this protocol gave inferior yields.

a) DMP, pyridine, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt; b) $\mathrm{MeLi}, \mathrm{NaBF}_{4}$, $\mathrm{THF},-78^{\circ} \mathrm{C}$, $24 \%$ (2 steps); c) MeMgCl , THF, $0^{\circ} \mathrm{C} \rightarrow \mathrm{rt}, 54 \%$ (2 steps).

Scheme 73

The addition of the methyl group was diasteroselective with attack of the ketone from the under face of the molecule as drawn. This was due once again to the bowl shape of the cladiellin skeleton forcing nucleophilic to attack from the convex face of the molecule. Diol (土)-320 was a crystalline solid and X-ray crystallography confirmed the relative configuration of the stereogenic centres in the molecule (Figure 17).

(土) -320
Figure 17

The synthesis of the diol (+)-320 meant that our next goal was the protection of the two tertiary alcohols as acetates. In his synthesis of ophirin B, Crimmins ${ }^{26}$ reported that the bis-acetylation of these two alcohols was problematic. It required a three-step procedure of acetylation, acetate migration and second acetylation (Scheme 12). In order to avoid such a problem at the end of our synthesis, we decided to acetylate the alcohols early in the synthesis. To
achieve this difficult bis-acetylation DMAP catalysed, base and solvent-free conditions were tested (Scheme 74). ${ }^{102}$ However, when the reaction was performed at room temperature, only the starting material (+)-320 was recovered. Attempts to increase the reactivity by raising the temperature to $60{ }^{\circ} \mathrm{C}$ only caused decomposition of the starting material.

Scheme 74

Crimmins and co-workers recently reported the synthesis of the proposed structure of briarellin J. ${ }^{103}$ This synthesis features the use of isopropenyl acetate as acetylation agent for the formation of the acetate of a hindered tertiary alcohol. This reaction was promoted by $p$-toluenesulfonic acid ( $p$-TSA) and has been used generally for the acetylation of tertiary alcohols. ${ }^{104}$ Using this protocol with our system would allow us to cleave the enol ether and protect the two hydroxyl groups in one step. Bis-acetate (+)-322 was formed in $59 \%$ yield by stirring diol (+)-320 with p-TSA in isopropenyl acetate as solvent (Scheme 75).

With the bis-acetate in place, our next goal was the formation of enone 270. Nicolaou and co-workers have developed an efficient IBX-mediated reaction for the oxidation of a ketone to give an enone. ${ }^{105}$ It was reported that this protocol could be used to oxidise cyclohexanones. However, treatment of ketone (+)-322 with IBX alone or complexed with 4 -picoline $N$-oxide, as reported by Nicolaou, did not yield the required enone 270. Only the ketone starting material (+)-322 was recovered in both cases.

a) isopropenyl acetate, $p$-TSA, rt, $59 \%$; b) IBX, toluene:DMSO 2:1, $65^{\circ} \mathrm{C}$; c) IBX, 4-picoline N -oxide, DMSO, $70^{\circ} \mathrm{C}$.

Scheme 75

In the light of the good results that had been obtained during the development of the tandem oxonium ylide formation and [2,3]-sigmatropic rearrangement reaction, and the difficulty encountered for the formation of enone 270 , it was decided to focus our effort on the synthesis of members of the E-cladiellin series. Indeed, the development of an efficient synthesis of the $E$-bicyclic ketone (-)-72 allowed us to target those cladiellins featuring a E-alkene or trans-1,2-diol on the medium-sized ring. This opened to us a wide range of new possible targets. Moreover only Kim and co-workers have reported a general strategy that can be applied to the synthesis of both $E$ - and $Z$-cladiellins and we were keen to demonstrate that our strategy offered the same flexibility.

### 2.3.2 Future Work for the Completion of the Synthesis of Ophirin B

Only five steps remain for the completion of the synthesis of ophirin B (Scheme 76). First, conditions would need to be identified to allow the formation of enone 270 from ketone (+)-322. Increasing the temperature of the reaction or using microwave activation could provide a solution to the problem of the poor reactivity of IBX. Epoxidation of the enone should deliver epoxy ketone 324. This epoxidation should be diasteroselective due to the bowl shape of the molecule. Subsequent Wittig methylenation and partial reduction of the resulting alkene 269 using $\mathrm{PtO}_{2} / \mathrm{H}_{2}$ should give allylic alcohol 326. Simple acetylation would then deliver ophirin $B$.

(+)-322

Ophirin B
$\cdots$

270

326

324

269

Scheme 76

If conditions for the oxidation for ketone (+)-322 to enone 270 cannot be found, an alternative route to enone 270 will have to be considered (Scheme 77). Starting from diol (+)-320 bis-TBS protection and subsequent acidic cleavage of the enol ether would form ketone 328. Then a Saegusa-Ito oxidation should deliver enone $330 .{ }^{106}$ Removal of the TBS-protecting groups and bis-acetylation of the tertiary alcohols should form enone 270. This synthesis of enone 270 should be relatively straightforward, but would require several more steps than the route presented in Scheme 76.

Scheme 77

### 2.4 Synthesis of the E-Cladiellin Natural Products

### 2.4.1 Formation of the Tricyclic Core found in the E-Cladiellins

Having successfully developed conditions that deliver the E-bicyclic ketone 72 with a good selectivity from diazoketone 70, the synthesis of the cladiellins possessing an E-alkene or trans-1,2-diol within the medium-sized ring was attempted. The first challenge was construction of the tricyclic core of the E-cladiellins.

The three-step sequence developed for the synthesis of the tricyclic core of the Z-cladiellins was first employed (Scheme 78). Enol triflate formation, Stille cross-coupling and Diels-Alder cycloaddition reaction protocol delivered the tricyclic ketone 335 in modest yield (34\%) over the three steps, as a 1.6:1 exo:endo mixture. Isomerisation of the endo:exo mixture with potassium carbonate afforded the desired exo product (土)-exo-335 in 85\% yield. The yield obtained for the formation of the tricyclic compound needed to be improved before attempting the rest of the synthesis. The low yield obtained in the synthesis of the tricyclic core appeared to be due to the instability of diene 334. Enol triflate 333 was indeed obtained without problem from ketone (土)-72, but considerable decomposition of intermediates was observed during both the Stille cross-coupling and the Diels-Alder reaction. In order to improve the overall yield during the synthesis of the $E$-tricyclic core, these two steps were optimised.

a) $\mathrm{NaHMDS}, \mathrm{PhN}(\mathrm{Tf})_{2}, \mathrm{THF},-78{ }^{\circ} \mathrm{C}$; b) $\mathrm{CH}_{2} \mathrm{C}(\mathrm{OEt}) \mathrm{SnBu}_{3}, \mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$, LiCl , THF, reflux; c) $\mathrm{CH}_{2} \mathrm{CHCOCH}_{3}$, toluene, reflux, $34 \%$ (3 steps), 1.6:1 exo:endo; d) $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{MeOH}$, rt, $85 \%$.

## Scheme 78

### 2.4.1.1 Studies Concerning Diene Formation

In order to avoid using a toxic and expensive organostannane and to be able to use a cheaper palladium source, the Heck coupling reaction was considered as an alternative to the Stille cross-coupling reaction (Scheme 79). Hallberg and co-workers have reported the coupling of vinyl ethers with enol triflates to synthesise 2 -alkoxy-1,3-butadienes. ${ }^{107}$ Applying these conditions in the crosscoupling of enol triflates ( $\mathbf{\pm}$ )-333 and ( $\mathbf{\pm}$ )-314 using palladium acetate as catalyst gave mixed results. Although diene ( $\pm$ )-74 was formed in $18 \%$ yield over two steps (enol triflate formation and Heck coupling), significant decomposition was observed using the same conditions on triflate ( $\pm$ )-333. This illustrates the difference in reactivity and stability of the two enol triflates, induced by the oxonene alkene geometry. Addition of 1,3-bis(diphenylphosphino)propane (DPPP) to the reaction mixture increased the yield to $60 \%$ over two steps for the synthesis of diene ( $\pm$ )-74 but once again only decomposition products were obtained from the reaction of enol triflate ( $\pm$ )-333.

a) $\mathrm{Pd}(\mathrm{OAc})_{2}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMSO}, 60^{\circ} \mathrm{C}$; b) $\mathrm{Pd}(\mathrm{OAc})_{2}, \mathrm{DPPP}^{2} \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMSO}, 60^{\circ} \mathrm{C}$.

Scheme 79

In order to spare valuable material, further optimisation reactions were performed using a model system. Formation of enol triflate 338 was achieved in 96\% yield, and this compound was used to test different palladium coupling conditions. Heck coupling delivered diene 339 in 74\% yield (Table 10, entry 1) but Stille cross-coupling with tributyl(1-ethoxyvinyl)tin using lithium chloride or copper iodide and cesium fluoride as additives afforded only decomposition products (entries 2, 3). ${ }^{108}$ Methyl ketone 340 was the main product isolated from the reaction mixture.

| Entry | Conditions | Outcome / Yield |
| :---: | :---: | :---: |
| 1 | $\mathrm{CH}_{2} \mathrm{CHOEt}, \mathrm{Pd}(\mathrm{OAC})_{2}, \mathrm{DPPP}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMSO}, 60{ }^{\circ} \mathrm{C}$ | $74 \%$ |
| 2 | $\mathrm{CH} \mathrm{H}_{2} \mathrm{C}(\mathrm{OEt}) \mathrm{SnBu}_{3}, \mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}, \mathrm{LiCl}, \mathrm{THF}$, reflux | Decomposition |
| 3 | $\mathrm{CH}_{2} \mathrm{C}(\mathrm{OEt}) \mathrm{SnBu}_{3},{\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}, \mathrm{CuI}, \mathrm{CsF}, \mathrm{THF}, \text { reflux }}^{c}$ Decomposition |  |
|  | Table 10 |  |

The inability to identify conditions for the more efficient synthesis of diene 334 meant that the focus shifted to optimisation of the Diels-Alder reaction.

### 2.4.1.2 Studies on the Diels-Alder Cycloaddition Reaction

Diels-Alder reactions can be promoted by altering various reaction parameters. One of the more common tricks is to carry the reaction without solvent. However, it was demonstrated earlier that for our system the reaction yield was higher at low concentration. Another frequent technique relies on the use of Lewis acid for the activation of dienophiles bearing electron withdrawing groups. ${ }^{109}$ Indeed, binding of a Lewis acid to the electron-withdrawing group of the dienophile lowers its LUMO resulting in an increase of reactivity.

The effect of different Lewis acids on the Diels-Alder cycloaddition of methyl vinyl ketone with our dienes was studied. First different Lewis acids were tested for the cycloaddition reaction between methyl vinyl ketone and the model diene 339 formed by Heck coupling (Table 11). The use of two equivalents of $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ at $-40{ }^{\circ} \mathrm{C}$ caused decomposition of diene 339 (entry 1 ). Lowering further the temperature to $-78{ }^{\circ} \mathrm{C}$ did not prevent the decomposition (entry 2 ) and use of catalytic amounts of $\mathrm{AlCl}_{3}$ at $-78{ }^{\circ} \mathrm{C}$ did not afford any bicyclic product 342 either (entry 3). Methyl ketone 340 was again the main product isolated from the reaction mixture.

| Entry | Conditions | Outcome |
| :---: | :--- | :---: |
| 1 | $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}(2 \mathrm{eq}), \mathrm{CH}_{2} \mathrm{Cl}_{2},-40{ }^{\circ} \mathrm{C}$ | Decomposition |
| 2 | $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}(2 \mathrm{eq}), \mathrm{CH}_{2} \mathrm{Cl}_{2},-78{ }^{\circ} \mathrm{C}$ | Decomposition |
| 3 | $\mathrm{AlCl}_{3}(10 \mathrm{~mol} \%), \mathrm{CH}_{2} \mathrm{Cl}_{2},-78{ }^{\circ} \mathrm{C}$ | Decomposition |

Table 11

In order to make sure that the decomposition was not due to the instability of the model diene 339, the fully functionalised substrates ( $\pm$ )-334 and ( $\pm$ )-74 were subjected to the Lewis acid catalysed Diels-Alder reaction with methyl vinyl ketone (Scheme 80). The $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ catalysed cycloaddition reaction of
diene (土)-334 with methyl vinyl ketone at $-78{ }^{\circ} \mathrm{C}$ gave only decomposition products. Adding $\mathrm{AlCl}_{3}$ and performing the reaction under thermal conditions used for the cycloaddition of diene ( $\mathbf{\pm}$ )-74 previously also caused decomposition of the starting material; methyl ketone ( $\mathbf{\pm}$ )-343 was the major product isolated from the reaction mixture.

$( \pm)-74$
$( \pm)-75$

$( \pm)$-343

Scheme 80

In the light of these results, it was clear that the dienes used, bearing the ethyl ether, were extremely unstable, especially in presence of Lewis acids. Another approach was then considered. Hoye and co-workers have reported the use of 1,1-dicarbonylalkene 344 as activated dienophile in Diels-Alder cycloaddition reactions. ${ }^{110}$ Cycloaddition of diene 334 with highly reactive dienophile 344 should afford tricycle 345 as a endo:exo mixture and subsequent decarboxylation should reveal the tricylic core 335 found in the E-cladiellins (Scheme 81).

Scheme 81

1,1-Dicarbonylalkene 344 was synthesised in four steps from methyl 2-bromopropionate 346 (Scheme 82). Nucleophilic substitution of 346 with thiophenol gave thioether 347 in $98 \%$ yield. Acylation of the $a$-phenylthio ester enolate with acetyl chloride yielded $B$-keto ester 348 in $80 \%$ yield. The thioether 348 was then oxidised with m-CPBA to give the non-isolated sulfoxide 349. Finally, thermolysis of sulfoxide 349 afforded 1,1-dicarbonylalkene 344, which was reported to be highly unstable and therefore kept in solution before the Diels-Alder reaction.

a) $\mathrm{PhSH}, \mathrm{NaH}, \mathrm{THF}, 0^{\circ} \mathrm{C}, 98 \%$; b) $\mathrm{LiHMDS}, \mathrm{CH}_{3} \mathrm{COCl}, \mathrm{THF},-78{ }^{\circ} \mathrm{C}, 80 \%, 91 \% \mathrm{brsm}$; c) $m$-CPBA, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$; d) $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \Delta$.

The reactivity of dienophile 344 was tested with both the model diene 339 and the bicyclic diene ( $\pm$ )-74 (Scheme 83). Sulfoxide 349 was heated in toluene at reflux for 30 min to form 1,1-dicarbonylalkene 344 before addition of either diene following Hoye's conditions. However in both cases only decomposition was observed. It was thought that the failure of the reactions could be due to the decomposition of alkene 344 prior to diene addition. In order to prevent such decomposition, sulfoxide 349 and diene 339 were directly stirred together in benzene at $80^{\circ} \mathrm{C}$ such that dienophile 344 could react with diene 339 as soon as it was formed. However, these conditions did not yield the desired Diels-Alder product 350 either.

Having failed to identify an efficient method for the construction of the tricyclic core of the E-cladiellins, an organocatalysed mode of activation was studied. MacMillan and co-workers have reported the use of imidazolidinone 355 as an efficient catalyst for the Diels-Alder cycloaddition of $a, B$-unsaturated ketones. ${ }^{111}$ The increase in reactivity results from formation of an iminium cation from the reaction of the $a, B$-unsaturated ketone and the imidazolidinone, which lowers the LUMO of the dienophile. Imidazolidinones 355 and 356 were formed in two
steps (Scheme 84). First methylamide 353 was obtained from L-phenylalanine 352 in $66 \%$ yield. ${ }^{112}$ The imidazolidinone ring was then formed by reaction of 353 with 5 -methylfurfural 354 . Both $(2 S, 5 S) 355$ and $(2 R, 5 S) 356$ imidazolidinone were obtained and separated by column chromatography.

$\mathrm{Sm}(\mathrm{OTf})_{3}$
4 A MS
THF, rt

355
20\%

356
19\%

Scheme 84

With imidazolidinone 355 in hand the organocatalysed Diels-Alder cycloaddition reaction was carried out (Scheme 85). The diene ( $\pm$ )-334 was stirred at $-30{ }^{\circ} \mathrm{C}$ with methyl vinyl ketone and imidazolidinone 355 ( $20 \mathrm{~mol} \%$ ) for ten hours, as no reaction was observed the mixture was slowly warmed up to $-10{ }^{\circ} \mathrm{C}$. After stirring at this temperature for eighteen hours it was warmed up to $-5{ }^{\circ} \mathrm{C}$ for 10 hours and finally stirred at room temperature. Unfortunately, none of the tricyclic product 335 was obtained out of the complex mixture of side products that was produced.

Having failed to optimise the formation of diene 334 and its Diels-Alder cycloaddition with methyl vinyl ketone, it was decided to revert back to the original protocol. The standard three-step procedure was employed, delivering this time a much improved $68 \%$ yield over three steps. The increase in the yield was explained through a combination of small experimental changes. Firstly as the high instability of the diene 334 had been demonstrated, especially its decomposition to the corresponding methyl ketone under acidic conditions, extra care was taken. An alternative, basic work-up was used for the Stille reaction, ${ }^{113}$ and no purification of the diene apart from a quick filtration through a small plug of silica treated with triethylamine to remove baseline impurities was done. Moreover, the tributyl(1-ethoxyvinyl)tin used was freshly prepared from ethyl vinyl ether and distilled prior to use, and not purchased from Aldrich. ${ }^{114}$ These optimised conditions afforded a good and reproducible yield.

## Scheme 86

Having finally found efficient conditions for the formation of tricyclic core of the E-cladiellins (+)-exo-335 our attention turned to the functionalisation of this core structure.

### 2.4.2 Formation of the Isopropyl Group

Our next challenge was the formation of the isopropyl group present on the six-membered ring of cladiella-6,11-dien-3-ol and many other cladiellins. As presented in the retrosynthetic analysis the addition of the C-3 methyl group and the formation of the C-11 trisubstituted alkene would be addressed last (Scheme 87). The proposed route towards the formation of the isopropyl group involved the formation of alkene 360 by Wittig olefination of methyl ketone exo- 335 followed by selective hydrogenation of the terminal alkene in presence of the trisubstituted one to form compound 358.

Scheme 87

Wittig olefination of ketone ( $\pm$ )-exo-335 delivered triene ( $\pm$ )- $\mathbf{3 6 0}$ in $80 \%$ yield (Scheme 88). Subsequent acidic cleavage of the enol ether in ( $\pm$ )- 360 produced ketone ( $\pm$ )-359 as a crystalline solid in $87 \%$ yield. X-ray crystallography of ( $\pm$ )-359 confirmed the relative configuration of the stereogenic centres in the molecule (Figure 18).

a) $\mathrm{Ph}_{3} \mathrm{PCH}_{3} \mathrm{Br}, \mathrm{NaHMDS}, \mathrm{THF}, \mathrm{rt}, 80 \%$; b) $1 \mathrm{M} \mathrm{HCl}, \mathrm{THF}, \mathrm{rt}, 87 \%$.

## Scheme 88

(土)-359
Figure 18

The selective hydrogenation of 76 a similar compound, had been achieved in $84 \%$ yield during the synthesis of vigulariol using platinum oxide and hydrogen at atmospheric pressure (Scheme 89). ${ }^{80}$

Scheme 89

The only difference between the two compounds 76 and ( $\pm$ )- 359 was the geometry of the oxonene alkene. Using these original conditions with diene ( $\pm$ )-359 resulted in decomposition of the starting material (Table 12, entry 1). Various catalysts including Wilkinson's catalyst (entry 2), titanocene dichloride
(entry 3) ${ }^{115}$ and Raney nickel (entry 4) were tested using an atmospheric pressure of hydrogen or the H -cube, but in all cases decomposition was obtained. A complicated mixture of Z-isomerised starting material and fully hydrogenated compound was observed in the reaction mixture.

|  |  |  <br> ( $\pm$ )-358 |  |
| :---: | :---: | :---: | :---: |
| Entry | Conditions | Method | Outcome |
| 1 | $\mathrm{PtO}_{2}$, EtOAc, rt | $\mathrm{H}_{2} \mathrm{~atm}$ | Decomposition |
| 2 | Wilkinson's catalyst, EtOH, rt | $\mathrm{H}_{2} \mathrm{~atm}$ | Decomposition |
| 3 | $\mathrm{Cp}_{2} \mathrm{TiCl}_{2}, \mathrm{Mg}$, THF, rt | $\mathrm{H}_{2} \mathrm{~atm}$ | Decomposition |
| 4 | Raney Ni , EtOH, rt | H-cube ${ }^{\text {a }}$ | Decomposition |
| 5 | $\mathrm{PtO}_{2}, \mathrm{EtOH}, \mathrm{rt}$ | H-cube ${ }^{\text {a }}$ | Decomposition |

Table 12

It was thought that the bulky TBS-protecting group was probably blocking access of the catalyst to the terminal alkene. To test this hypothesis the silyl protecting group was removed using TBAF to deliver the primary alcohol ( $\pm$ )-363 in $72 \%$ yield (Scheme 90). However, once again, treatment of ( $\pm$ )-363 with platinum oxide under an atmosphere of hydrogen caused isomerisation and decomposition of the starting material.

a) TBAF, THF, rt, $72 \%$; b) $\mathrm{PtO}_{2}, \mathrm{H}_{2}$ atm, EtOAc, rt.

Further observation of the 3D structure of diene ( $\pm$ )-359 obtained by X-ray crystallography revealed that the E-trisubstituted oxonene alkene had a $22^{\circ}$ torsion angle explaining its reactivity with respect to hydrogenation. This torsion angle can be seen in Figure 19, where the view is made in line with the oxonene double bound.

(土)-359
Figure 19

Having been unable to form the isopropyl group by selective alkene hydrogenation, alternative approaches were considered. First, selective hydroboration of the terminal alkene of diene ( $\pm$ )-359 with $9-\mathrm{BBN}$ followed by acidic treatment was explored (Scheme 91). ${ }^{116}$ However, this reaction resulted in decomposition.

( $\pm$ )-359

Scheme 91

A new route for the introduction of the isopropyl group was designed starting from the Diels-Alder product exo-335 (Scheme 92). Reduction of the methyl ketone would give the secondary alcohol 365, and the hydroxyl group would
then be transformed into a good leaving group. Cuprate displacement of the leaving group would then form 367, bearing the isopropyl moiety. ${ }^{117}$

Scheme 92

Reduction of ketone ( $\pm$ )-exo- 335 with sodium borohydride delivered alcohol ( $\pm$ )- 365 in 78\% yield as a 1: 1.9 mixture of diastereomers (Scheme 93). The two diastereomers were separated by column chromatography. Treatment of the secondary alcohol ( $\pm$ )-365 with mesyl or tosyl chloride failed to deliver any product ( $\pm$ )-368 or ( $\pm$ )-369; in both cases only decomposition was observed. To prevent decomposition, the triflate intermediate was formed and used directly in the cuprate displacement reaction. Treatment of alcohol ( $\pm$ )- 365 with triflic anhydride at $-78{ }^{\circ} \mathrm{C}$ delivered the triflate which was not isolated but kept at $-78{ }^{\circ} \mathrm{C}$ before being treated with a solution of $\mathrm{Me}_{2} \mathrm{CuLi}$ obtained by stirring together methyl lithium and copper iodide. Unfortunately, once again, only decomposition was observed.

( $\pm$-exo-335

( $\pm$ )-365

$( \pm)-367$
a) $\mathrm{NaBH}_{4}, \mathrm{MeOH}: \mathrm{CH}_{2} \mathrm{Cl}_{2} 1: 1$, rt, $78 \%$, dr (1:1.9); b) $\mathrm{MsCl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0{ }^{\circ} \mathrm{C}$; c) TsCl , DMAP, pyridine, $0^{\circ} \mathrm{C} \rightarrow \mathrm{rt}$; d) i) 2,6 -lutidine, $\mathrm{Tf}_{2} \mathrm{O}, \mathrm{Et}_{2} \mathrm{O},-78^{\circ} \mathrm{C}$; ii) MeLi, Cul, $-78^{\circ} \mathrm{C} \rightarrow 0^{\circ} \mathrm{C}$.

Scheme 93

Due to the failure of the cuprate displacement, an alternative route to compound 358 was proposed (Scheme 94). Starting from the Diels-Alder product exo-335, Grignard addition to the ketone and subsequent acidic hydrolysis of the enol ether would form tertiary alcohol 370 . Compound 358 bearing the isopropyl moiety could then be obtained by reductive deoxygenation of the tertiary alcohol 370 using triethylsilane or by Barton-McCombie deoxygenation.

Scheme 94

Grignard addition of methyl magnesium bromide to the methyl ketone ( $\pm$ )-exo- 335 afforded the tertiary alcohol ( $\pm$ )- 372 in $78 \%$ yield (Scheme 95). Acidic treatment of enol ether ( $\pm$ )- 372 gave a mixture of the desired ketone $( \pm)-370$ and the cyclised product $( \pm)-373$. Formation of the tetracyclic product was explained by the attack of the suitably positioned hydroxypropyl group into the intermediate oxonium ion. A similar cyclisation process had been reported by Crimmins and co-workers during their synthesis of ophirin B (Scheme 11). ${ }^{26}$

a) $\mathrm{MeMgBr}, \mathrm{THF}, 0^{\circ} \mathrm{C} \rightarrow \mathrm{rt}, 78 \%$; b) $\mathrm{HCl}, \mathrm{THF}, \mathrm{rt}, 43 \% \mathbf{3 7 0}, 17 \% 373$.

Scheme 95

With tertiary alcohol ( $\mathbf{\pm}$ )-370 formed, the two deoxygenation techniques were investigated (Scheme 96). Direct reductive deoxygenation of ( $\mathbf{\pm}$ )-370 using triethylsilane and $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ did not afford the desired product $( \pm)-358$, but gave a complex mixture composed of $Z$-isomerised and desilylated starting material. ${ }^{118}$ The second technique considered was the Barton-McCombie
deoxygenation, but the xanthate intermediate ( $\mathbf{\pm}$ )-371 could not be formed from the hindered tertiary alcohol ( $\mathbf{\pm}$ )-370 using standard conditions. ${ }^{119}$

$( \pm)-370$

( $\pm$ )-370

( $\pm$ )-358

( $\pm$ )-371

Scheme 96

In order to test whether the failure of the xanthate formation was due to the difficulty to deprotonate the tertiary alcohol, a one-pot procedure to form the xanthate ( $\pm$ )-374 from methyl ketone ( $\mathbf{\pm}$ )-exo-335 was explored (Scheme 97). First, nucleophilic attack at the carbonyl centre was performed with methyl lithium to form the lithiated intermediate. Upon complete consumption of the ketone starting material, carbon disulfide and methyl iodide were added to the reaction mixture to react with the lithiated intermediate. Unfortunately, this one-pot procedure did not afforded any of the xanthate product ( $\pm$ )-374 either.

Scheme 97

Looking back at the previous total syntheses of cladiellin natural products, it was observed that Kim and co-workers had reported that the formation of the
isopropyl group in presence of the reactive $6 E$-oxonene alkene was a challenge during the synthesis of cladiella-6,11-dien-3-ol. ${ }^{31}$ Kim and co-workers succeeded in forming the isopropyl group in 65 by converting tertiary alcohol 375 into the corresponding acetate 376 and subjecting this tertiary acetate to dissolving metal reduction conditions (Scheme 98). ${ }^{120}$

a) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt; b) $\mathrm{K}, 18$-crown- $6, t-\mathrm{BuNH}_{2}, \mathrm{THF}, \mathrm{rt}, 62 \%$ (2 steps).

Scheme 98

Applying the same protocol to our substrate seemed possible. The enol ether (+)-372 was selected as the starting material in order to avoid formation the tetracyclic side-product 373 (Scheme 95). Synthesis of the tertiary acetate 377 was achieved by treatment of alcohol (+)-372 with acetic anhydride as solvent, DMAP and triethylamine at $40{ }^{\circ} \mathrm{C}$ (Scheme 99). A solution of acetate 377 in THF was then added to the deep blue solution resulting from the solvation of the potassium metal by 18 -crown-6 in tert-butylamine and THF. After reappearance of the royal-blue colour, the remaining potassium metal was carefully quenched by the addition of absolute ethanol. The reaction delivered compound (+)-378 having lost the TBS-protecting group in $65 \%$ yield over two steps. The cleavage of the TBS ether was due to the very basic conditions generated upon quenching of the remaining potassium metal. Various conditions were explored to prevent deprotection during the destruction of the excess of the potassium metal, but all failed. The dissolving metal reduction reaction was highly moisture sensitive and in order to obtain the royal-blue solution the crown ether used had to be carefully recrystallised from acetonitrile and thoughtfully vacuum dried, and the potassium metal had to be cut and transfered into the reaction mixture coated in oil.

a) $\mathrm{MeMgBr}, \mathrm{THF}, 0^{\circ} \mathrm{C} \rightarrow \mathrm{rt}, 78 \%$; b) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, 40^{\circ} \mathrm{C}$; c) $\mathrm{K}, 18$-crown- $6, t-\mathrm{BuNH}_{2}, \mathrm{THF}$, rt, 65\% (2 steps).

Scheme 99

Having successfully synthesised alcohol (+)-378 bearing the desired isopropyl moiety on the six-membered ring, the final functional group modifications were performed.

### 2.4.3 Completion of the Synthesis of Cladiella-6,11-dien-3-ol

Following the successful synthesis of the alcohol (+)-378 the next goal was formation of the trisubtituted alkene present in the six-membered ring of cladiella-6,11-dien-3-ol. It was proposed to build this alkene via a Kumada coupling. ${ }^{121}$ Hydrolysis of the enol ether (+)-378 under acidic conditions afforded ketone (-)-364 in $89 \%$ yield (Scheme 100). The yield of this reaction was improved by performing it after the deoxygenation reaction in order to prevent formation of the tetracyclic side-product 373. Protection of the secondary alcohol as TBS ether was achieved in 78\% yield.

a) $\mathrm{HCl}, \mathrm{THF}, \mathrm{rt}, 89 \%$; b) TBSOTf, 2,6 -lutidine, $\mathrm{CH}_{2} \mathrm{Cl}_{2},-78^{\circ} \mathrm{C}, 78 \%$.

Scheme 100

Formation of the kinetic enol triflate 379 was achieved by treatment of ketone (-)-358 with a solution of NaHMDS in presence of $\mathrm{PhNTf}_{2}$ at $-78{ }^{\circ} \mathrm{C}$ (Scheme 101). The vinyl triflate was used in a palladium(0) mediated Kumada
cross-coupling reaction with methyl magnesium chloride to afford diene 357 bearing the desired trisubstituted alkene in the six-membered ring. ${ }^{122}$ Diene 357 was highly non-polar and could not be separated from the triphenylphosphine impurities resulting from the palladium catalyst. Treatment of the crude diene 357 with TBAF afforded the secondary alcohol (+)-380. This product being more polar than 357 could be easily purified to give $68 \%$ yield over three steps for the formation of the trisubstituted alkene.

a) $\left.\left.\mathrm{NaHMDS}, \mathrm{PhN}(\mathrm{Tf})_{2}, \mathrm{THF},-78{ }^{\circ} \mathrm{C} ; \mathrm{b}\right) \mathrm{MeMgCl}, \mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}, \mathrm{LiCl}, \mathrm{THF}, \mathrm{rt} ; \mathrm{c}\right)$ TBAF, $4 \AA \mathrm{MS}, \mathrm{THF}, \mathrm{rt}, 68 \%$ (3 steps).

Scheme 101

Compound 65 (Scheme 14, 98), the C-3 epimer of alcohol (+)-380 had been reported by Kim and co-workers as a late stage intermediate in their synthesis of (-)-cladiella-6,11-dien-3-ol. ${ }^{31}$ Completion of the synthesis of (-)-cladiella-6,11-dien-3-ol was accomplished in two additional steps involving oxidation of the secondary alcohol to the corresponding ketone followed by a methyl group addition (Scheme 102). As a similar cyclic ketone had been found to be unstable during our work towards the synthesis of ophirin $B$, it was decided to use the crude ketone 381 obtained from Dess-Martin oxidation of (+)-380 directly in the methylation reaction. Standard Grignard addition of methyl magnesium chloride to the crude ketone 381 afforded (-)-cladiella-6,11-dien-3-ol in $58 \%$ over the two steps. This yield was improved to $69 \%$ over two steps by the use of the Paquette protocol ${ }^{22}$ involving the reaction of the crude ketone 381 with methyl lithium in presence of sodium tetrafluoroborate at $-78{ }^{\circ} \mathrm{C}$. In both cases the
addition was highly diastereoselective, with the nucleophile attacking form convex (back) side of the molecule. The spectroscopic and other characterisation data of synthetic (-)-cladiella-6,11-dien-3-ol were identical to those reported for the natural product.

a) DMP, pyridine, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt; b) MeMgCl , THF, $0^{\circ} \mathrm{C} \rightarrow \mathrm{rt}, 58 \%$ (2 steps); c) MeLi, $\mathrm{NaBF}_{4}$, THF, $-78^{\circ} \mathrm{C}, 69 \%$ (2 steps).

Scheme 102

As previously reported by Kim and co-workers (-)-cladiell-11-ene-3,6,7-triol was formed by selective Upjohn dihydroxylation of the $6 E$-oxonene alkene of (-)-cladiella-6,11-dien-3-ol (Scheme 103). Kim demonstrated that this dihydroxylation is selective for the more reactive $6 E$-oxonene alkene; this high reactivity results from the torsion angle of the alkene caused by the ring strain. This process is also diasteroselective with attack from the convex (back) side of the molecule due to the bowl shape and the rigidity of the $6 E$-oxonene ring. The triol was obtained as a single diastereomer in 66\% yield by treatment of the diene with 2 mol\% of osmium tetroxide and N -methylmorpholine- N -oxide (NMO) as stoichiometric oxidant. The reaction was followed carefully by TLC in order to prevent over-oxidation of the compound to give the corresponding quintaol. The spectroscopic and other characterisation data of synthetic (-)-cladiell-11-ene-$3,6,7$-triol were identical to those reported for the natural product. ${ }^{123}$ Moreover the triol was isolated as a colourless crystalline solid allowing a X-ray crystal structure to be obtained (Figure 20).

Scheme 103

(-)-Cladiell-11-ene-3,6,7-triol
Figure 20

Our next target was (-)-acetoxycladiella-6,11-diene as this natural product had never been synthesised before. Acetylation of the hindered tertiary alcohol proved to be difficult. Treatment of (-)-cladiella-6,11-dien-3-ol with triethylamine and DMAP, using acetic anhydride as solvent at $40^{\circ} \mathrm{C}$ afforded the acetate in a modest $25 \%$ yield (Table 13, entry 1 ). Substituting acetic anhydride for acetyl chloride in dichloromethane gave a complicated decomposition mixture (entry 2). Using more powerful, Lewis acid catalysed acylation conditions did not afford any of the desired acetate. ${ }^{124}$ Instead treatment of (-)-cladiella-6,11-dien-3-ol with acetic anhydride and TMSOTf as catalyst produced oxatetracycle (+)-382 in 84\% yield (entry 3). Such ether ring formation had already been reported with the use of Lewis acids by Hochlowski and Faulkner ${ }^{9}$ and Kim and co-workers had reported the formation of (+)-382 during the synthesis of polyanthellin A. ${ }^{31}$ The shape of the molecule implies that the tertiary alcohol is very close to the alkene, which upon activation formed the ether ring. Despite the low yield of the acetylation reaction due to the position of the tertiary alcohol hindered inside the bowl created by the molecule skeleton, (-)-3-acetoxycladiella-6,11-diene was synthesised for the first time. Spectroscopic and other characterisation data were identical to those reported for the natural product.

| Entry | Conditions | Outcome / Yield |
| :---: | :---: | :---: |
| 1 | $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{Ac}_{2} \mathrm{O}$ as solvent, $40{ }^{\circ} \mathrm{C}$ | $25 \%$ |
| 2 | $\mathrm{AcCl}^{\circ}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}$ | decomposition |
| 3 | $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{TMSOTf}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0{ }^{\circ} \mathrm{C}$ | $81 \%$ of $(+)-\mathbf{3 8 2}$ |

Table 13

With the small quantity of (-)-3-acetoxycladiella-6,11-diene available, the synthesis of 3-acetoxycladiellin-11-ene-6,7-diol was attempted. Selective Upjohn dihydroxylation of the $6 E$-oxonene alkene was carried out as in the case of the synthesis of (-)-cladiell-11-ene-3,6,7-triol (Scheme 104). Treatment of (-)-3-acetoxycladiella-6,11-diene with catalytic quantities of $\mathrm{OsO}_{4}$ in presence of NMO as a stoichiometric oxidant at $0{ }^{\circ} \mathrm{C}$ afforded 3-acetoxycladiellin-11-ene-6,7diol in $36 \%$ yield and this is the first reported synthesis of this particular natural product. Due to the lack of starting material this reaction was not optimised but nevertheless, enough 3-acetoxycladiellin-11-ene-6,7-diol was obtained to prove that the spectroscopic and other characterisation data were identical to those reported for the natural product. ${ }^{125}$ Due to the low concentration in which the optical rotation was carried out and our instrument sensitivity we were unable to determine the sign of the optical rotation, our measurements oscillating around $0,[\alpha]^{28} 0\left(c=0.30, \mathrm{CHCl}_{3}\right)\left\{\mathrm{Lit}^{12}[\alpha]_{\mathrm{D}}-1.87\left(c=2.17, \mathrm{CHCl}_{3}\right)\right\}$.

(-)-3-Acetoxycladiella-6,11-diene
3-Acetoxycladiellin-11-ene-6,7-diol

Scheme 104

Having completed the enantioselective total syntheses of four members of the cladiellin family of natural products featuring an endo-cyclic alkene in the
six-membered ring, our focus then turned to the synthesis of other members of this family of natural products.

### 2.4.4 Synthesis of Cladiellins Containing an exo-Cyclic Alkene

Following the synthesis of four cladiellins bearing a cyclic trisustituted alkene on the six-membered ring, the versatility of our synthetic route was tested through the selection of four other related natural product bearing an exo-cyclic alkene on the six-membered ring (Scheme 105). Sclerophytin A and B have had their structures corrected by the simultaneous syntheses of Paquette ${ }^{23}$ and Overman ${ }^{15}$ and have been chosen has targets by many groups, unlike cladiellin or litophytin A for which no syntheses have yet been reported. It was postulated that these four compounds could be formed from the same intermediate, alcohol 383. Removal of the C-3 methyl group of 383 would reveal secondary alcohol 384, which could be obtained by deoxygenation of acetate 385 . Acetate 385 could be formed from methyl ketone exo-335, the synthesis of which has already been presented in this thesis.

$R=H$, sclerophytin A $R=A c$, sclerophytin $B$ $\qquad$

$R=A c, \quad$ cladiellin $R=$ COPr, litophynin A

exo-335

385

Scheme 105

The synthesis of the targets started as previously by a Grignard addition to the methyl ketone (+)-exo-335 delivering the tertiary alcohol (+)-372. Subsequent acetylation of the tertiary alcohol was performed as previously reported and followed by acidic enol ether hydrolysis to afford ketone 386 (Scheme 106). Formation of the exocyclic alkene was obtained by Wittig olefination of ketone 386. Subjecting the tertiary acetate 385 to the dissolving metal conditions presented previously afforded diene (+)-384 in 47\% yield over 4 steps.

a) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}$, DMAP, $40^{\circ} \mathrm{C}$; b) HCl , THF, rt; c) $\mathrm{Ph}_{3} \mathrm{PCH}_{3} \mathrm{Br}, \mathrm{NaHMDS}$, THF, reflux, d) $\mathrm{K}, 18$-crown-6, $t$-BuNH 2 , THF, rt, $47 \%$ ( 4 steps).

Scheme 106

With diene (+)-384 formed, only the introduction of the methyl group at C-3 remained to obtain the tertiary alcohol (-)-383, the common intermediate to the four natural product targets. This was achieved in two steps by oxidation of secondary alcohol with Dess-Martin periodinane followed by methyl addition (Scheme 107). The two standard methyl addition conditions were tested and once again the Paquette protocol ${ }^{22}$ using methyl lithium and sodium tetrafluoroborate at $-78{ }^{\circ} \mathrm{C}$ afforded tertiary alcohol ( - )- 383 with the best yield (78\% over the two steps).

a) DMP, pyridine, $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt; b) $\mathrm{MeMgCl}, \mathrm{THF}, 0^{\circ} \mathrm{C} \rightarrow \mathrm{rt}, 42 \%$ (2 steps); c) MeLi, $\mathrm{NaBF}_{4}$, THF, $-7{ }^{\circ} \mathrm{C}, 78 \%$ (2 steps).

Scheme 107

Alcohol (-)-383 was not itself a natural product but, as in the case of (-)-cladiella-6,11-dien-3-ol, it could be transformed into several cladiellin natural products (Scheme 108). Dihydroxylation of (-)-383 should afford sclerophytin A which itself would give sclerophytin B. Esterification of the tertiary alcohol in (-)-383 with acetic anhydride or butanoyl chloride should form cladiellin and litophytin A respectively.

Selective Upjohn dihydroxylation of the trisubstituted alkene in presence of the terminal alkene of (-)-383 was performed using the same conditions as for the synthesis of (-)-cladiell-11-ene-3,6,7-triol and afforded (-)-sclerophytin A in 59\% yield (Scheme 109). Once again this process was chemoselective for the trisubstituted oxonene and diastereoselective with dihydroxylation occurring from the convex face of the molecule. The spectroscopic and other characterisation data for synthetic (-)-sclerophytin A were identical to those reported for the natural product. As previously reported by Paquette, ${ }^{23}$ selective
acetylation of the secondary alcohol in presence of the two tertiary alcohols afforded (-)-sclerophytin B in 79\% yield. Synthetic (-)-sclerophytin B had spectroscopic and other characterisation data that were identical to those previously reported.

a) $\mathrm{OsO}_{4}, \mathrm{NMO}, \mathrm{THF}: \mathrm{H}_{2} \mathrm{O} 1: 1,0^{\circ} \mathrm{C} \rightarrow \mathrm{rt}, 59 \%$; b) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}, 79 \%$.

Scheme 109

Esterification of the tertiary alcohol (-)-383 was then attempted. Initially it was decided to target the synthesis of litophytin A but the esterification of the hindered tertiary alcohol proved to be problematic. Treatment of alcohol (-)-383 with butanoyl chloride, triethylamine and DMAP afforded a complex mixture from which the required product could not be isolated. Given the size of the butanoyl moiety it was decided to target cladiellin instead of litophynin A because acetylation of this tertiary alcohol should be easier.

Scheme 110

Having successfully accomplished the acetylation of (-)-cladiella-6,11-dien-3-ol, a compound very similar to the alcohol (-)-383, it was thought that using the same conditions on (-)-383 would afford cladiellin (Table 14). It was known that this alcohol was highly hindered and acetylation was expected to proceed in low yield. Initially similar conditions to those used in the synthesis of (-)-3-acetoxycladiella-6,11-diene were attempted. Alcohol (-)-383 was stirred in acetic anhydride with triethylamine and DMAP at room temperature and at $40{ }^{\circ} \mathrm{C}$ but in both cases only a complex mixture of side-products was obtained
(Table 14, entries 1 and 2). Performing the reaction in dichloromethane at room temperature did not afford the required product either (entry 3). Attempts to deprotonate the tertiary alcohol with potassium hydride prior to the addition of acetic anhydride or acetic anhydride and DMAP did not afford any of the desired acetate (entries 4 and 5). Changing the acetylating agent from acetic anhydride to acetyl chloride did not improve the reaction (entry 6). Finally, the use isopropenyl acetate in the presence of $p$-TSA as the acetylating agent ${ }^{103,104}$ was attempted, but only oxatetracycle (-)-388 was obtained in this case. This compound had been reported by Paquette ${ }^{23}$ and co-workers during their synthesis of the original structure of sclerophytin A and the spectroscopic data of oxatetracycle (-)-388 matched that reported previously, confirming the configuration of the ring. Formation of the ether ring can be explained as in the case of the Lewis acid induced cyclisation of (+)-382 from cladiella-6-11-dien-3ol (Table 13). Due to the bowl shape of the molecule and the ring strain, the hydroxyl group is held close to the trisubstituted alkene and upon treatment with a Brønsted acid the oxygen attacks the activated alkene to form the ether ring.

Despite having investigated a wide range of acetylation conditions, the synthesis of cladiellin was not achieved. The fact that the conditions employed in the synthesis of (-)-3-acetoxycladiella-6,11-diene failed to deliver the required ester (entry 2) suggested that the exo-cyclic alkene on the six-membered ring has changed the conformation of the molecule to the extent that the tertiary hydroxyl group is buried more deeply inside the bowl created by the bridge ether system.

Table 14

Despite the failure to esterify the tertiary alcohol (-)-383 to deliver cladiellin and litophytin A, the screening of acetylation conditions had revealed an efficient synthesis of oxatetracycle ( - )-388. This extra ether-ring is present in some natural products of the cladiellin family, such as deacetylpolyanthellin A and polyanthellin A. These two natural products were synthesised from oxatetracycle (+)-382 [a regioisomer of (-)-388] by Kim and co-workers ${ }^{31}$ and so their oxymercuration-demercuration conditions were tested on the oxatetracycle (-)-388 (Scheme 111). Treatment of (-)-388 with $\mathrm{Hg}(\mathrm{OAc})_{2}$ in a 1:1 mixture THF:water was followed by low temperature demercuration with sodium borohydride and triethylborane ${ }^{126}$ affording (+)-deacetylpolyanthellin A in $77 \%$ yield, as a 10:1 mixture of diastereomers. The diastereoselectivity of the oxymercuration was lower with substrate (-)-388 possessing an exocyclic alkene compared to that reported by Kim with the oxatetracycle (+)-382 possessing an endocyclic trisubstituted alkene, probably due to the difference in the shape of the molecule. Acetylation of the tertiary alcohol was achieved using acetic anhydride as solvent, triethylamine and DMAP delivering (+)-polyanthellin A in $55 \%$ yield. Both enantiomers of deacetylpolyanthellin A and polyanthellin A exist in the nature and the present synthesis provided the dextrorotary compound as reported by Kim, Johnson and Bowden. ${ }^{13,} 31,36,127$ Spectroscopic and other
characterisation data for both synthetic (+)-deacetylpolyanthellin A and $(+)$-polyanthellin A were identical to those reported for the natural products.

a) i) $\mathrm{Hg}(\mathrm{OAc})_{2}, \mathrm{THF}: \mathrm{H}_{2} \mathrm{O} 1: 1$, rt; ii) $\mathrm{NaBH}_{4}, \mathrm{Et}_{3} \mathrm{~B}, \mathrm{THF}: \mathrm{H}_{2} \mathrm{O} 4: 1,-20^{\circ} \mathrm{C}, 77 \%$, dr 10:1; b) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}, \mathrm{rt}, 55 \%$.

Scheme 111

Despite the failure to synthesise of cladiellin and litophytin A, the tertiary alcohol (-)-383 was successfully used in the synthesis of four natural products: sclerophytin $A$ and $B$, deacetylpolyanthellin $A$ and polyanthellin A.

## 3 Summary and Future Work

### 3.1 Summary

The enantioselective total synthesis of eight natural products from the cladiellin family; (-)-cladiella-6,11-dien-3-ol, (-)-cladiell-11-ene-3,6,7-triol, (-)-3-acetoxycladiella-6,11-diene, 3-acetoxycladiellin-11-ene-6,7-diol, (-)-sclerophytin A, (-)-sclerophytin B, (+)-deacetylpolyanthellin A and (+)-polyanthellin A have been accomplished in 20 to 24 steps and 3\% overall yield from allylic alocohol precursor (+)-284. These syntheses featured three important ring-forming reactions to construct the tricyclic core of the cladiellins. Firstly, a $\mathrm{Sml}_{2}$-mediated reductive cyclisation formed the tetrahydropyran, then a tandem oxonium ylide formation and [2,3]-sigmatropic rearrangement reaction constructed the oxabicyclo[6.2.1]undecenone bicyclic core. Finally a Diels-Alder cycloaddition reaction formed the third ring of the tricyclic core of the cladiellins.

The development of a scalable and efficient synthesis of the enantiopure allylic alcohol precursor (+)-284 has permitted the formation of sufficient quantities of material for completion of the asymmetric total syntheses of the targets.

Studies on the tandem oxonium ylide formation and [2,3]-sigmatropic rearrangement reaction have allowed the development of conditions for the selective formation of either the $E$ - or Z-bicyclic ketone $\mathbf{7 2} 73$. It is now possible to tune the reaction to obtain selectively the $E$-bicyclic ketone 72 , using rhodium(II) triphenylacetate, or the Z-bicyclic ketone 73, with copper(II) hexafluoroacetylacetonate as catalyst.

Seventeen steps have been accomplished towards the synthesis of the Z-cladiellin ophirin B from allylic alcohol precursor (+)-284. An efficient bisacetylation of the tertiary alcohols has been achieved, and only five steps remain to complete the asymmetric total synthesis of this natural product.

The tricyclic core of the E-cladiellin has been obtained in good yield allowing its synthesis in multi-gram quantities. Further functionalisation of the tricycle core, and in particular the formation of the isopropyl group present on six-membered ring has allowed the completion of the synthesis of the targets.

### 3.2 Future work

Future work should concentrate on the completion of the synthesis of ophirin B as proposed in Chapter 2.3.2. This synthesis would demonstrate even further the versatility of our synthetic route by the synthesis of a cladiellin bearing a 6Z-oxonene alkene.

Ongoing computational calculations on the stability of the various intermediates and possible transition states for the oxonium ylide formation and [2,3]-sigmatropic rearrangement reaction will deliver a more detailed understanding of this transformation and account for the selectivity obtained with the different catalysts.

Some of the natural products that have been synthesised will be sent for biological evaluation in order to discover if they have any interesting pharmaceutical properties, especially anti-cancer activity.

Finally, using the strategy developed during the project, the synthesis of other 2,11-cyclised cembranoid natural products such as the briarellins and cladiellins will be undertaken. Of particular interest will be cladiellins having a S-configuration at the C-3 carbon. These compounds, such as sclerophytin E and $F$, have had their structures reassigned by Paquette and co-workers and only total synthesis would confirm this reassignment (Scheme 112). ${ }^{6}$ Sclerophytin E and F could be obtained using a similar synthetic route where the C-3 methyl group would be installed just after the $\mathrm{Sml}_{2}$-cyclisation. This modified route would also allow the effect that the C-3 centre has on the outcome of the oxonium ylide formation and [2,3]-sigmatropic rearrangement reaction to be assessed.

Sclerophytin E \& F $\quad \Longrightarrow$

## 4 Experimental

## General comment

Air and/or moisture sensitive reactions were performed under an atmosphere of Argon in flame dried apparatus. Organic solvents were dried using a Pure Solv ${ }^{\mathrm{M}}$ solvent purification systems. All reagents were purchased from commercial suppliers and used without further purification, unless otherwise stated. All reactions were monitored by thin layer chromatography using Merck silica gel 60 covered alumina plates $F_{254}$. Thin layer chromatography plates were viewed under UV light or were visualised using either potassium permanganate solution or acidic ethanolic anisaldehyde solution. Column chromatography was performed under pressure using silica gel (Fluorochem LC60A, 35-70 micron, 60A) as solid support and HPLC-graded solvents as eluent. Petroleum ether used for column chromatography was $40-60{ }^{\circ} \mathrm{C}$ fraction.

IR spectra were recorded using a type lla diamond single reflection element on a Shimadzu FTIR-8400 instrument. The IR spectrum of the compound (solid or liquid) was directly detected as a thin layer at ambient temperature.
${ }^{1} \mathrm{H}$ NMR spectra were recorded on a Bruker 400 MHz or 500 MHz Spectrospin spectrometer at ambient temperature. The carbon numbering drawn on the molecule corresponds to the cladiellin numbering used for the NMR signal assignment. IUPAC numbering is used for the molecule names. Data are reported as follows: chemical shift in ppm relative to $\mathrm{CDCl}_{3}$ (7.27) on the $\delta$ scale, integration, multiplicity ( $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=\mathrm{quartet}, \mathrm{m}=$ multiplet, $\mathrm{br}=$ broad, or a combination of these), coupling constant(s) $\mathrm{J}(\mathrm{Hz})$ and assignment. ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker 400 MHz or 500 MHz Spectrospin spectrometer at 100 MHz or 125 MHz at ambient temperature and multiplicities were obtained using a DEPT sequence. Data are reported as follows: chemical shift in ppm relative to $\mathrm{CHCl}_{3}$ (77.16) on the $\delta$ scale and assignment.

High resolution mass spectra (HRMS) were obtained under EI, FAB, CI and ES conditions by the analytical services of the University of Glasgow on a Jeol MStation JMS-700 instrument. Low resolution mass spectra (LRMS) were carried
out on the same instrument; the intensity of each peak is quoted as a percentage of the largest, where this information was available.

Elemental analyses were carried out on an Exeter Analytical Elemental Analyser EA 440.

Melting points were recorded with an Electrothermal IA 9100 apparatus.

## (3-Bromopropoxy)(tert-butyl)dimethylsilane 67

To a stirred solution of 3-bromopropanol $285(30.0 \mathrm{~g}, 216 \mathrm{mmol})$, TBSCl ( 38.8 g , 259 mmol ) and DMAP ( 90 mg ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(450 \mathrm{~mL})$ at rt was added triethylamine ( $39.3 \mathrm{~g}, 389 \mathrm{mmol}$ ). The resulting solution was stirred at rt 18 h before being diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(100 \mathrm{~mL})$. The organic layer was separated and washed with water ( $2 \times 200 \mathrm{~mL}$ ), $1 \mathrm{M} \mathrm{HCl}(200 \mathrm{~mL})$, water $(200 \mathrm{~mL})$ and brine ( 200 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give a colourless oil. Vacuum distillation (b.p. $94-96{ }^{\circ} \mathrm{C}$ at 14 mmHg ) \{Lit. ${ }^{128} 182^{\circ} \mathrm{C}$ at 760 mmHg$\}$ furnished the bromide $67(44.3 \mathrm{~g}, 86 \%)$ as a colourless oil.
${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 3.73\left(2 \mathrm{H}, \mathrm{t}, \mathrm{J}=5.7 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 1\right), 3.51(2 \mathrm{H}, \mathrm{t}$, $\left.J=6.4 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 3\right), 2.03\left(2 \mathrm{H}, \mathrm{tt}, J=6.4,5.7 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 2\right), 0.89\left(9 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{tBu}\right)$, $0.07\left(6 \mathrm{H}, \mathrm{s}, \mathrm{SiCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 60.6\left(\mathrm{CH}_{2}-\mathrm{C} 1\right), 35.7\left(\mathrm{CH}_{2}-\mathrm{C} 2\right)$, $30.9\left(\mathrm{CH}_{2}-\mathrm{C} 3\right), 26.1\left(\mathrm{CH}_{3}-t \mathrm{Bu}\right), 18.5(\mathrm{C}-t \mathrm{Bu}),-5.2\left(\mathrm{SiCH}_{3}\right) ; \operatorname{HRMS}\left(\mathrm{CI}, \mathrm{Me}_{3} \mathrm{CH}\right)$ $[\mathrm{M}+\mathrm{H}]^{+}$for $\mathrm{C}_{9} \mathrm{H}_{22} \mathrm{O}^{79} \mathrm{BrSi}$ calcd 253.0624, found 253.0626, $\Delta+1.1 \mathrm{ppm}$; LRMS (CI, $\mathrm{Me}_{3} \mathrm{CH}$ ) m/z (intensity) 255.3 (10\%), 253.3 (10\%), 89.2 (100\%); IR $\mathrm{v}_{\max }$ 2955, 2929, 2857, 951, 832, $774 \mathrm{~cm}^{-1}$.

## 6-tert-Butyldimethylsilyloxy-2-methyl-1-hexen-3-ol 284

To a stirred slurry of magnesium turnings ( $2.8 \mathrm{~g}, 86 \mathrm{mmol}$ ) and iodine (trace) in anhydrous THF ( 12 mL ) was added bromide $67(20 \mathrm{~g}, 78 \mathrm{mmol})$ in anhydrous THF ( 130 mL ) dropwise. After complete addition, the resulting brown solution was stirred for a further 1 h before freshly distilled methacrolein ( $2.7 \mathrm{~g}, 39 \mathrm{mmol}$ ) in anhydrous THF ( 8 mL ) was added dropwise over 30 min . The resulting solution was stirred for further 1 h and then quenched by the addition of a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(160 \mathrm{~mL})$ and $\mathrm{Et}_{2} \mathrm{O}(120 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 80 \mathrm{~mL})$. The organic extracts were
combined, washed with brine ( 160 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to yield a colourless oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, 5:1) afforded the alcohol 284 as a colourless oil ( $8.8 \mathrm{~g}, 93 \%$ ).
$\mathrm{R}_{f}=0.42$ (petroleum ether - ethyl acetate, $5: 1$ ); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 4.96$ (1H, br s, CH2-C6), 4.83 (1H, br s, CH2-C6), 4.08-4.04 (1H, m, CH-C4), 3.66 ( 2 H , $\left.\mathrm{t}, \mathrm{J}=5.7 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 1\right), 2.53(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=3.8 \mathrm{~Hz}, \mathrm{OH}), 1.72\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 7\right)$, 1.71-1.56 (4H, m, CH2-C2, CH2-C3), $0.90(9 \mathrm{H}, \mathrm{s}, t \mathrm{Bu}), 0.06\left(6 \mathrm{H}, \mathrm{s}, \mathrm{SiCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR (100 MHz, $\left.\mathrm{CDCl}_{3}\right) ~ \delta 147.7(\mathrm{C}-\mathrm{C} 5), 110.9\left(\mathrm{CH}_{2}-\mathrm{C} 6\right), 75.6(\mathrm{CH}-\mathrm{C} 4), 63.5$ $\left(\mathrm{CH}_{2}-\mathrm{C} 1\right), 32.5\left(\mathrm{CH}_{2}-\mathrm{C} 3\right), 29.0\left(\mathrm{CH}_{2}-\mathrm{C} 2\right), 26.1\left(\mathrm{CH}_{3}-t \mathrm{Bu}\right), 18.5(\mathrm{C}-t \mathrm{Bu}), 18.0$ $\left(\mathrm{CH}_{3}-\mathrm{C} 7\right),-5.2\left(\mathrm{SiCH}_{3}\right)$; HRMS $\left(\mathrm{Cl}, \mathrm{Me}_{3} \mathrm{CH}\right)[\mathrm{M}+\mathrm{H}]^{+}$calcd for $\mathrm{C}_{13} \mathrm{H}_{29} \mathrm{O}_{2} \mathrm{Si}$ 245.1937, found 245.1932, $\Delta$-2.1 ppm; LRMS (CI, Me ${ }_{3} \mathrm{CH}$ ) m/z (intensity) 245.5 ( $80 \%$ ), 227.4 (100\%), 137.3 (60\%), 113.3 (80\%); Anal. ## 4-(tert-Butyldimethylsilyl)oxy-1-butanol 303

To a stirred solution of butandiol $302(33.8 \mathrm{~g}, 375 \mathrm{mmol})$ and triethylamine ( $37.9 \mathrm{~g}, 375 \mathrm{mmol}$ ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(750 \mathrm{~mL}$ ) was added $\mathrm{TBSCl}(37.7 \mathrm{~g}$, 250 mmol ). The resulting solution was stirred 18 h at rt and the reaction was then quenched by the addition of a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(250$ $\mathrm{mL})$. The aqueous phase was separated and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 100 \mathrm{~mL})$. The organic extracts were combined and washed with brine $(100 \mathrm{~mL})$ then dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to yield a colourless oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, gradient elution $8: 1 \rightarrow 5: 1$ ) afforded the alcohol $303(45.9 \mathrm{~g}, 90 \%)$ as a colourless oil.
$R_{f}=0.53$ (petroleum ether - ethyl acetate, $1: 1$ ); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 3.69-3.62 (4H, m, CH2-C1, CH $\left.\mathrm{Cl}_{2}-\mathrm{C} 4\right), 2.46(1 \mathrm{H}, \mathrm{br}$ s, OH$), 1.68-1.61(4 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{CH}_{2}-\mathrm{C} 2, \mathrm{CH}_{2}-\mathrm{C} 3\right), 0.90(9 \mathrm{H}, \mathrm{s}, ~ t B u), 0.07\left(6 \mathrm{H}, \mathrm{s}, \mathrm{SiCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR (100 MHz, $\left.\mathrm{CDCl}_{3}\right)$; б $63.5\left(\mathrm{CH}_{2}-\mathrm{C} 4\right), 62.9\left(\mathrm{CH}_{2}-\mathrm{C} 1\right), 30.4\left(\mathrm{CH}_{2}-\mathrm{C} 3\right), 30.0\left(\mathrm{CH}_{2}-\mathrm{C} 2\right), 26.0$ $\left(\mathrm{CH}_{3}-t \mathrm{Bu}\right), 18.4(\mathrm{C}-t \mathrm{Bu}),-5.3\left(\mathrm{CH}_{3}-\mathrm{SiCH}_{3}\right)$; $\mathrm{HRMS}\left(\mathrm{Cl}, \mathrm{Me}_{3} \mathrm{CH}\right)[\mathrm{M}+\mathrm{H}]^{+}$for $\mathrm{C}_{10} \mathrm{H}_{25} \mathrm{O}_{2} \mathrm{Si}$ calcd 205.1625, found 205.1621, $\Delta-1.5 \mathrm{ppm}$; LRMS ( $\mathrm{Cl}, \mathrm{Me}_{3} \mathrm{CH}$ ) m/z (intensity); 205.4 (100\%), 137.2 (40\%), 121.2 (18\%); IR $v_{\max } 3348$, 2953, 2929, 2858, 835, 775 $\mathrm{cm}^{-1}$.
(E)-6-(tert-Butyldimethylsilanyloxy)-2-methyl-hex-2-enoic acid ethyl ester $305{ }^{80,86}$

To a stirred solution of oxalyl chloride ( $33.0 \mathrm{~g}, 373 \mathrm{mmol}$ ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 640 mL ) cooled at $-78^{\circ} \mathrm{C}$ was added slowly a solution of anhydrous DMSO ( 40.0 mL , 562 mmol ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(200 \mathrm{~mL})$ and the resulting solution was stirred for 30 min . The alcohol 303 ( $31.0 \mathrm{~g}, 152 \mathrm{mmol}$ ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}$
$(460 \mathrm{~mL})$ was then added dropwise. The resulting solution was stirred at the same temperature for a further 2 h and then quenched with triethylamine (76.8 $\mathrm{g}, 760 \mathrm{mmol}$ ) at $-78{ }^{\circ} \mathrm{C}$. The reaction mixture was allowed to warm to rt and stirred for 30 min then diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(500 \mathrm{~mL})$ and water ( 300 mL ). The aqueous phase was separated and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 150 \mathrm{~mL})$. The organic extracts were combined and washed with brine ( 300 mL ) then dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to afford the crude aldehyde 304 which was used for the next step without purification.

To a stirred solution of the crude aldehyde 304 in anhydrous THF (1.5 L) was added ethyl 2-(triphenylphosphoranylidene)propanoate ( $82.5 \mathrm{~g}, 227 \mathrm{mmol}$ ) in one portion. The resulting solution was stirred at rt for 48 h and the reaction was then quenched by the addition of ethyl acetate ( 500 mL ) and water ( 500 mL ). The aqueous phase was separated and extracted with ethyl acetate ( $3 \times$ $300 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 300 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to yield a white solid. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, 20:1) afforded the alkene 305 ( $40.8 \mathrm{~g}, 95 \%$ over two steps) as a colourless oil.
$\mathrm{R}_{f}=0.77$ (petroleum ether - ethyl acetate, $2: 1$ ); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 6.77$ (1H, tq, J = 7.5, 1.4 Hz, CH-C4), 4.18 ( $2 \mathrm{H}, \mathrm{q}, ~ J=7.1 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{Et}$ ), $3.62(2 \mathrm{H}, \mathrm{t}$, $\left.J=6.2 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 1\right), 2.26-2.21\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}-\mathrm{C} 3\right), 1.82(3 \mathrm{H}, \mathrm{br} \mathrm{d}, \mathrm{J}=1.4 \mathrm{~Hz}$, $\left.\mathrm{CH}_{3} \mathrm{C} 7\right), 1.65\left(2 \mathrm{H}, \mathrm{tt}, \mathrm{J}=7.6,6.2 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 2\right), 1.30\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.1 \mathrm{~Hz}, \mathrm{CH}_{3}-\mathrm{Et}\right)$, 0.89 (9H, s, tBu), $0.04\left(6 \mathrm{H}, \mathrm{s}, \mathrm{SiCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ); ס $168.4(\mathrm{C}-\mathrm{C} 6)$, 142.0 (CH-C4), 128.2 (C-C5), $62.5\left(\mathrm{CH}_{2}-\mathrm{C} 1\right), 60.5\left(\mathrm{CH}_{2}-\mathrm{Et}\right), 31.8\left(\mathrm{CH}_{2}-\mathrm{C} 3\right), 26.1$ $\left(\mathrm{CH}_{3}-t \mathrm{Bu}\right), \quad 25.2\left(\mathrm{CH}_{2}-\mathrm{C} 2\right), \quad 18.4(\mathrm{C}-\mathrm{tBu}), \quad 14.5\left(\mathrm{CH}_{3}-\mathrm{Et}\right), 12.5\left(\mathrm{CH}_{3}-\mathrm{C} 7\right)$, $-5.2\left(\mathrm{CH}_{3}-\mathrm{SiCH}_{3}\right)$; HRMS $\left(\mathrm{Cl}, \mathrm{Me}_{3} \mathrm{CH}\right)[\mathrm{M}+\mathrm{H}]^{+}$for $\mathrm{C}_{15} \mathrm{H}_{31} \mathrm{O}_{3} \mathrm{Si}$ calcd 287.2044, found 287.2041, $\Delta$-0.4 ppm; LRMS (CI, Me ${ }_{3} \mathrm{CH}$ ) m/z (intensity); 287.3 (100\%), 241.3 (18\%), 229.3 (11\%); Anal. ## (R)-6-tert-Butyldimethylsilyloxy-2-methyl-1-hexen-3-ol $284^{80,86}$

To a stirred solution of the epoxy alcohol 307 ( $30.3 \mathrm{~g}, 117 \mathrm{mmol}$ ) and triethylamine ( $17.7 \mathrm{~g}, 175 \mathrm{mmol}$ ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(580 \mathrm{~mL})$ at $-10{ }^{\circ} \mathrm{C}$ was slowly added methanesulfonyl chloride ( $16.0 \mathrm{~g}, 140 \mathrm{mmol}$ ). The solution was stirred for 10 min then quenched by the addition of water $(100 \mathrm{~mL})$ and diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(250 \mathrm{~mL})$. The organic phase was washed with brine $(100 \mathrm{~mL})$, dried ( $\mathrm{MgSO}_{4}$ ), filtered and concentrated in vacuo to yield a colourless oil. The crude epoxy mesylate 308 was carried on to the next step without further purification. To a stirred solution of the crude epoxy mesylate 308 in butan-2-one ( 580 mL ) was added sodium iodide ( $87.4 \mathrm{~g}, 583 \mathrm{mmol}$ ) and the reaction mixture was heated at reflux for 1 h giving a brown slurry. Zinc powder ( $11.4 \mathrm{~g}, 175 \mathrm{mmol}$ ) was then added and the reaction was stirred at reflux for a further 1 h giving a grey solution. The reaction mixture was then allowed to cool to rt, diluted with ethyl acetate $(500 \mathrm{~mL})$ and a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(300 \mathrm{~mL})$. The aqueous phase was separated and extracted with ethyl acetate ( $3 \times 300 \mathrm{~mL}$ ). The organic extracts were combined, washed with brine ( 300 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to yield a brown oil. Flash column chromatography on silica gel (petroleum ether - diethyl ether, gradient elution 30:1 $\rightarrow$ 20:1 $\rightarrow$ 15:1) afforded the alcohol 284 as a colourless oil ( $27.6 \mathrm{~g}, 97 \%$ over two steps). A 94\% enantiomeric purity of 284 was obtained by normal phase chiral HPLC analysis ${ }^{84}$ of the corresponding vinylogous carbonate 297.
$\mathrm{R}_{f}=0.42$ (petroleum ether - ethyl acetate, $5: 1$ ); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 4.96$ (1H, br s, CH2-C6), 4.83 ( $1 \mathrm{H}, \mathrm{br}$ s, $\mathrm{CH}_{2}-\mathrm{C} 6$ ), $4.08-4.04(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}-\mathrm{C} 4), 3.66(2 \mathrm{H}$, $\left.\mathrm{t}, \mathrm{J}=5.7 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 1\right), 2.53(1 \mathrm{H}, \mathrm{d}, \mathrm{J}=3.8 \mathrm{~Hz}, \mathrm{OH}), 1.72\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 7\right)$, 1.71-1.56 (4H, m, CH2-C2, CH2-C3), $0.90(9 \mathrm{H}, \mathrm{s}, t \mathrm{Bu}), 0.06\left(6 \mathrm{H}, \mathrm{s}, \mathrm{SiCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR (100 MHz, $\left.\mathrm{CDCl}_{3}\right) ~ \delta 147.7$ (C-C5), $110.9\left(\mathrm{CH}_{2}-\mathrm{C} 6\right), 75.6$ (CH-C4), 63.5 $\left(\mathrm{CH}_{2}-\mathrm{C} 1\right), 32.5\left(\mathrm{CH}_{2}-\mathrm{C} 3\right), 29.0\left(\mathrm{CH}_{2}-\mathrm{C} 2\right), 26.1\left(\mathrm{CH}_{3}-t \mathrm{Bu}\right), 18.5(\mathrm{C}-t \mathrm{Bu}), 18.0$ $\left(\mathrm{CH}_{3}-\mathrm{C} 7\right),-5.2\left(\mathrm{SiCH}_{3}\right)$; HRMS $\left(\mathrm{Cl}, \mathrm{Me}_{3} \mathrm{CH}\right)[\mathrm{M}+\mathrm{H}]^{+}$calcd for $\mathrm{C}_{13} \mathrm{H}_{29} \mathrm{O}_{2} \mathrm{Si}$ 245.1937, found 245.1932, $\Delta$-2.1 ppm; LRMS (CI, Me ${ }_{3} \mathrm{CH}$ ) m/z (intensity) 245.5 ( $80 \%$ ),

## 1-Diazo-3-[(2R,3S,6R)-3-(tert-butyldimethylsilyloxy)-6-isopropenyl tetrahydropyran-2-yl]-propan-2-one $70^{80}$

To a stirred solution of the carboxylic acid 312 ( $3.00 \mathrm{~g}, 9.55 \mathrm{mmol}$ ) and triethylamine ( $1.32 \mathrm{~g}, 13.0 \mathrm{mmol}$ ) in anhydrous diethyl ether ( 120 mL ) was added isobutyl chloroformate ( $1.64 \mathrm{~g}, 12.0 \mathrm{mmol}$ ) dropwise and the resulting solution was stirred for 2.5 h (a white precipitate formed). The solution of the anhydride was filtered under suction, washing the residue with diethyl ether, and then immediately added to a freshly prepared ethereal solution of diazomethane ( $\sim 100 \mathrm{mmol}$ ) dropwise. The solution was stirred for 2 days and quenched by addition of glacial acetic acid ( 5 mL ) then poured into a saturated aqueous solution of $\mathrm{NaHCO}_{3}(200 \mathrm{~mL})$ and vigorously stirred for 15 min . The aqueous phase was separated and extracted with ethyl acetate ( $3 \times 75 \mathrm{~mL}$ ). The combined organic extracts were washed with brine ( 75 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give a yellow oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate 10:1) afforded the diazo ketone 70 as a yellow oil ( $2.83 \mathrm{~g}, 88 \%$ ).

314

To a solution of the bicyclic ketone $73(1.06 \mathrm{~g}, 3.31 \mathrm{mmol})$ and $\mathrm{PhN}(\mathrm{Tf})_{2}(2.44 \mathrm{~g}$, 6.82 mmol ) in anhydrous THF ( 70 mL ) at $-78{ }^{\circ} \mathrm{C}$ was added NaHMDS ( 8.53 mL of a 1.0 M solution in THF, 8.53 mmol ) dropwise over 10 min . The resulting solution was stirred at $-78{ }^{\circ} \mathrm{C}$ for 2 h , then quenched with water $(20 \mathrm{~mL})$ at $-78{ }^{\circ} \mathrm{C}$ and
allowed to warm to rt. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 80 \mathrm{~mL})$. The organic extracts were combined washed with brine ( 40 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give the crude enol triflate 314 as a yellow oil which as used without any further purification in the next step.

To a solution of the above crude enol triflate 314 and $\mathrm{CH}_{2} \mathrm{C}(\mathrm{OEt}) \mathrm{SnBu}_{3}(3.69 \mathrm{~g}$, 10.2 mmol ) in anhydrous THF ( 70 mL ) was added $\mathrm{LiCl}(434 \mathrm{mg}, 10.2 \mathrm{mmol}$ ) and $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}(591 \mathrm{mg}, 510 \mu \mathrm{~mol})$, the solution was heated at reflux overnight. The reaction mixture was cooled and diluted with ethyl acetate ( 30 mL ). The organic phase was washed with brine ( 20 mL ), $5 \%$ aqueous solution of $\mathrm{NH}_{4} \mathrm{OH}(20 \mathrm{~mL})$, brine ( 20 mL ). The organic extracts were dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, filtered and concentrated in vacuo to give a yellow oil. Quick flash column chromatography on silica gel (petroleum ether - ethyl acetate, 15:1 with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) afforded the highly unstable diene 74 as a colourless oil which was used immediately.

The above diene 74 and freshly distilled methyl vinyl ketone ( $2.39 \mathrm{~g}, 34.1 \mathrm{mmol}$ ) were dissolved in anhydrous toluene ( 140 mL ) and heated to reflux in a sealed tube overnight. The volatiles were removed in vacuo to give a yellow oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, 15:1 with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) delivered a endo-exo mixture of Diels-Alder cycloadducts 75 ( 1.02 g , 69\% over 3 steps) as colourless oil.

To a stirred solution of the endo-exo mixture of cycloadducts 75 ( 1.02 g , 2.35 mmol ) in methanol ( 25 mL ) was added potassium carbonate ( $389 \mathrm{mg}, 2.80$ mmol ) and the solution stirred at rt overnight. The reaction mixture was diluted with a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(25 \mathrm{~mL})$ and ethyl acetate ( 40 mL ). The aqueous phase was separated and extracted with ethyl acetate ( $2 \times 40 \mathrm{~mL}$ ). The organic extracts were combined and washed with brine ( 20 mL ) then dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give a yellow oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, 20:1 with $1 \%$ $E t_{3} \mathrm{~N}$ ) afforded the ketone exo-75 as a colourless oil ( $929 \mathrm{mg}, 91 \%$ ).

320
322

To a solution of diol $320(10 \mathrm{mg}, 28 \mu \mathrm{~mol})$ in freshly distilled isopropenyl acetate ( 2 mL ) was added $p$-toluenesulfonic acid monohydrate ( $22 \mathrm{mg}, 0.11 \mathrm{mmol}$ ). The reaction mixture was stirred at rt 24 h before being quenched with a saturated aqueous solution of $\mathrm{NaHCO}_{3}(2 \mathrm{~mL})$ and diluted with ethyl acetate $(2 \mathrm{~mL})$. The aqueous phase was separated and extracted with ethyl acetate $(3 \times 3 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 3 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (petroleum ether - ethyl acetate, gradient elution 10:1 $\rightarrow 7: 1$ ) to deliver the ketone 322 ( $7 \mathrm{mg}, 59 \%$ ) as a colourless solid.
$\mathrm{R}_{f}=0.54$ (petroleum ether - ethyl acetate, 1:1); m.p. $132-135^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) ס 5.53 (1H, dd, J = 10.9, $6.2 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 6$ ), 4.75-4.72 (1H, m, CH-C9), 4.06 (1H, d, J = $9.0 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 2), 3.26$ (1H, dd, J = 9.0, $9.0 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 1$ ), 2.83 ( $1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=9.0,2.5 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 10$ ), $2.78\left(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=14.8 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 8\right)$, 2.63-2.48 (3H, m, CH2-C4, CH2-C5, CH2-C12), 2.35 (1H, ddd, J = 16.0, 5.0, 5.0 $\mathrm{Hz}, \mathrm{CH}_{2}-\mathrm{C} 12$ ), 2.14-1.97 (4H, m, CH2-C5, CH2-C13, CH-C14), 1.95 (3H, s, CH $\mathrm{CH}_{3}-\mathrm{Ac}$ ), $1.94\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{Ac}\right), 1.88\left(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=14.8,4.5 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 8\right), 1.78(3 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{CH}_{3}-\mathrm{C} 19\right)$, 1.76-1.70 (1H, m, CH -C 4 ), $1.74\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 18\right)$, $1.65(3 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{CH}_{3}-\mathrm{C} 16\right), 1.64\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 17\right) ;{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) ס $210.7(\mathrm{C}-\mathrm{C} 11)$, 169.9 (C-Ac), 169.8 (C-Ac), 131.0 (C-C7), 130.0 (CH-C6), 86.4 (C-C3), 86.1 (CH-C2), 85.2 (C-C15), 77.9 (CH-C9), 54.4 (CH-C10), 43.3 (CH-C1), 42.6 (CH-C14), $37.6\left(\mathrm{CH}_{2}-\mathrm{C} 8\right), 36.7\left(\mathrm{CH}_{2}-\mathrm{C} 12\right), 34.4\left(\mathrm{CH}_{2}-\mathrm{C} 4\right), 28.3\left(\mathrm{CH}_{3}-\mathrm{C} 19\right), 25.9$ ( $\left.\mathrm{CH}_{3}-\mathrm{C} 17\right)$, $24.9\left(\mathrm{CH}_{3}-\mathrm{C} 16\right), 23.9\left(\mathrm{CH}_{3}-\mathrm{C} 18\right), 22.9\left(\mathrm{CH}_{3}-\mathrm{Ac}\right), 22.8\left(\mathrm{CH}_{3}-\mathrm{Ac}\right), 22.7$ $\left(\mathrm{CH}_{2}-\mathrm{C} 5\right), 21.9\left(\mathrm{CH}_{2}-\mathrm{C} 13\right)$; IR $v_{\max }$ 2966, 2344, 2332, 1734, 1706, $1559 \mathrm{~cm}^{-1} ;[\alpha]^{25}{ }_{\mathrm{D}}$ $+7.0\left(c=1.00, \mathrm{CHCl}_{3}\right)$.

72

334

333

To a solution of the $E$-ketone $72(1.53 \mathrm{~g}, 4.93 \mathrm{mmol})$ and $\operatorname{PhN}(\mathrm{Tf})_{2}(3.52 \mathrm{~g}$, 9.87 mmol ) in anhydrous THF ( 100 mL ) at $-78{ }^{\circ} \mathrm{C}$ was added $\mathrm{NaHMDS}(12.4 \mathrm{~mL}$ of a 1.0 M solution in THF, 12.4 mmol ) dropwise over 10 min . The resulting solution was stirred at $-78{ }^{\circ} \mathrm{C}$ for 2 h then quenched with water ( 30 mL ) at $-78{ }^{\circ} \mathrm{C}$ and allowed to warm to rt. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 80 \mathrm{~mL})$. The organic extracts were combined and washed with brine $(60 \mathrm{~mL})$ then dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give the crude enol triflate 333 as a yellow oil.

To a solution of the above crude enol triflate 333 and $\mathrm{CH}_{2} \mathrm{C}(\mathrm{OEt}) \mathrm{SnBu}_{3}(5.35 \mathrm{~g}$, 14.8 mmol ) in anhydrous THF ( 100 mL ) was added $\mathrm{LiCl}(628 \mathrm{mg}, 14.8 \mathrm{mmol}$ ) and $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}(856 \mathrm{mg}, 740 \mu \mathrm{~mol})$ and the solution was heated at reflux overnight. The reaction mixture was cooled and diluted with ethyl acetate ( 50 mL ). The organic phase was washed with brine ( 30 mL ), $5 \%$ aqueous solution of $\mathrm{NH}_{4} \mathrm{OH}$ $(30 \mathrm{~mL})$ and brine ( 30 mL ). The organic extract were dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, filtered and concentrated in vacuo to give a yellow oil. Quick flash column chromatography on silica gel (petroleum ether - ethyl acetate, $15: 1$ with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) afforded the highly unstable diene 334 as a colourless oil which was used immediately.

The above diene 334 and freshly distilled methyl vinyl ketone ( 3.45 g , 49.3 mmol ) were dissolved in anhydrous toluene ( 200 mL ) and heated at $130{ }^{\circ} \mathrm{C}$ in a sealed tube overnight. The volatiles were removed in vacuo to give a yellow oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate,

15:1 with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) delivered an endo-exo mixture of Diels-Alder cycloadducts 335 ( 1.47 g , 68\% over 3 steps) as colourless oil.

To a stirred solution of the endo-exo mixture of cycloadducts $(1.44 \mathrm{~g}, 3.31$ mmol ) in methanol ( 35 mL ) was added potassium carbonate ( $550 \mathrm{mg}, 3.97 \mathrm{mmol}$ ) and the solution stirred at rt overnight. The reaction mixture was diluted with a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(35 \mathrm{~mL})$ and ethyl acetate $(60 \mathrm{~mL})$. The aqueous phase was separated and extracted with ethyl acetate $(2 \times 50 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 30 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give a yellow oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, 20:1 with $1 \%$ $\mathrm{Et}_{3} \mathrm{~N}$ ) afforded the ketone exo-335 as a colourless oil ( $1.22 \mathrm{~g}, 85 \%$ ).
$\mathrm{R}_{f}=0.30$ (petroleum ether - ethyl acetate, $5: 1$ ); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 5.67$ (1H, t, J = 8.4 Hz, CH-C6), 4.84 (1H, d, J = 6.0 Hz, CH-C9), 3.91 (1H, dd, J = 8.3, $4.9 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 2), 3.80\left(1 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CH}_{2}\right.$-Et), 3.79 ( $1 \mathrm{H}, \mathrm{q}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CH}_{2}$-Et), 3.66 ( $1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=6.3,4.9 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 3$ ), $2.68-2.62(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}-\mathrm{C} 1), 2.49(1 \mathrm{H}$, dd, $J=13.5,6.0 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 8$ ), 2.35-1.96 (8H, m, CH2-C4, CH2-C5, CH2-C8, CH2-C12, $\mathrm{CH}_{2}-\mathrm{C} 13, \mathrm{CH}-\mathrm{C} 14$ ), 2.15 (3H, s, $\mathrm{CH}_{3}-\mathrm{C} 16$ ), $1.70-1.59$ ( $2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}-\mathrm{C} 4, \mathrm{CH}_{2}-\mathrm{C} 13$ ), $1.65\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 17\right), 1.23\left(3 \mathrm{H}, \mathrm{t}, \mathrm{J}=7.0 \mathrm{~Hz}, \mathrm{CH}_{3}-\mathrm{Et}\right), 0.92\left(9 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{tBu}\right)$, $0.05\left(3 \mathrm{H}, \mathrm{s}, \mathrm{SiCH}_{3}\right), 0.04\left(3 \mathrm{H}, \mathrm{s}, \mathrm{SiCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $\left.100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 211.7$ (C-C15), 143.3 (C-C11), 130.6 (CH-C6), 125.5 (C-C7), 121.3 (C-C10), 88.0 (CH-C2), 74.7 ( $\mathrm{CH}-\mathrm{C} 9), 74.0(\mathrm{CH}-\mathrm{C} 3), 63.3\left(\mathrm{CH}_{2}-\mathrm{Et}\right), 52.9(\mathrm{CH}-\mathrm{C} 14), 43.5$ $\left(\mathrm{CH}_{2}-\mathrm{C} 8\right), 42.8(\mathrm{CH}-\mathrm{C} 1), 30.3\left(\mathrm{CH}_{3}-\mathrm{C} 16\right), 28.9\left(\mathrm{CH}_{2}-\mathrm{C} 13\right), 27.1\left(\mathrm{CH}_{2}-\mathrm{C} 4\right), 26.1$ $\left(\mathrm{CH}_{3}-t \mathrm{Bu}\right), 24.4\left(\mathrm{CH}_{2}-\mathrm{C} 12\right), 21.6\left(\mathrm{CH}_{2}-\mathrm{C} 5\right), 18.5(\mathrm{C}-t \mathrm{Bu}), 18.3\left(\mathrm{CH}_{3}-\mathrm{C} 17\right), 15.7$ $\left(\mathrm{CH}_{3}-\mathrm{Et}\right),-4.5\left(\mathrm{SiCH}_{3}\right),-4.6\left(\mathrm{SiCH}_{3}\right)$; HRMS $\left(\mathrm{Cl}, \mathrm{Me}_{3} \mathrm{CH}\right)[\mathrm{M}+\mathrm{H}]^{+}$calcd for $\mathrm{C}_{25} \mathrm{H}_{43} \mathrm{O}_{4} \mathrm{Si}$ 435.2930, found 435.2922, $\Delta-2.0 \mathrm{ppm}$; LRMS (CI, $\mathrm{Me}_{3} \mathrm{CH}$ ) m/z (intensity) 435.7 (100\%), 303.6 (10\%), 113.3 (20\%); Anal. 4-Phenylcyclohex-1-en-1-yl trifluoromethanesulfonate 338

To a stirred solution of the 4-phenylcyclohexanone 337 ( $1.00 \mathrm{~g}, 5.73 \mathrm{mmol}$ ) and $\mathrm{PhN}(\mathrm{Tf})_{2}(4.09 \mathrm{~g}, 11.5 \mathrm{mmol})$ in anhydrous THF ( 110 mL ) at $-78{ }^{\circ} \mathrm{C}$ was added NaHMDS ( 14.4 mL of a 1.0 M solution in THF, 14.4 mmol ) dropwise over 10 min . The resulting solution was stirred for 2 h before being quenched with water ( 35 mL ) at $-78{ }^{\circ} \mathrm{C}$ and allowed to warm to rt . The aqueous layer was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 75 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 75 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give the crude enol triflate as a yellow oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, $98: 2$ with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) afforded the enol triflate 338 ( $1.69 \mathrm{~g}, 96 \%$ ) a colourless solid.
$\mathrm{R}_{f}=0.80$ (petroleum ether - ethyl acetate, $5: 1$ ); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 7.35-7.19 (5H, m, CH-Ar), 5.87-5.83 (1H, m, CH-C2), 2.91-2.80 (1H, m, CH-C4), 2.61-2.25 (4H, m, CH2-C3, CH2-C6), 2.11-2.01 (1H, m, CH2-C5), 2.01-1.89 (1H, $\left.\mathrm{m}, \mathrm{CH}_{2}-\mathrm{C} 5\right) ;{ }^{19} \mathrm{~F}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta-73.71\left(\mathrm{CF}_{3}\right)$; ${ }^{13} \mathrm{C}$ NMR $\left(100 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta$ 149.1 (C-C1), 144.7 (C-Ar), 128.8 (CH-Ar), 126.9 (CH-Ar), 126.8 (CH-Ar), 118.7 ( $\mathrm{q}, \mathrm{J}=320 \mathrm{~Hz}, \mathrm{CF}_{3}$ ), 118.3 ( $\mathrm{CH}-\mathrm{C} 2$ ), 38.9 ( $\left.\mathrm{CH}-\mathrm{C} 4\right), 31.7\left(\mathrm{CH}_{2}-\mathrm{C} 6\right), 29.8\left(\mathrm{CH}_{2}-\mathrm{C} 5\right)$, $28.0\left(\mathrm{CH}_{2}-\mathrm{C} 3\right)$; HRMS (EI) [M] ${ }^{+}$for $\mathrm{C}_{13} \mathrm{H}_{13} \mathrm{~F}_{3} \mathrm{O}_{3} \mathrm{~S}$ calcd 306.0540, found 306.0540, $\Delta+0.9$ ppm; LRMS (EI) m/z (intensity) 306.0 (20\%), 115.0 (18\%), 104.0 (100\%); IR $\mathrm{v}_{\max } 3030,2926,1691,1602,891,856,759 \mathrm{~cm}^{-1}$.

A mixture of palladium acetate ( $8.0 \mathrm{mg}, 39 \mu \mathrm{~mol}$ ), 1,3-bis(diphenylphosphino) propane ( $16 \mathrm{mg}, 39 \mu \mathrm{~mol}$ ) and molecular sieves in anhydrous DMSO ( 1 mL ) was stirred at rt for 30 min. Freshly distilled triethylamine ( $99 \mathrm{mg}, 0.97 \mathrm{mmol}$ ) was then added, followed by ethyl vinyl ether ( $94 \mathrm{mg}, 1.3 \mathrm{mmol}$ ) and a solution of the vinyltriflate 338 ( $0.20 \mathrm{~g}, 0.65 \mathrm{mmol}$ ) in anhydrous DMSO ( 1 mL ). The reaction mixture was stirred overnight at $60{ }^{\circ} \mathrm{C}$ and then poured into a 1 M solution of $\mathrm{NaOH}(3 \mathrm{~mL})$. The aqueous layer was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 10 \mathrm{~mL})$. The organic extracts were dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The undesired enone 340 was obtained as a colourless solid instead of the expected diene 339 .

## Methyl 2-(phenylsulfanyl)propanoate 347

To a solution of sodium hydride ( $60 \%$ in mineral oil, $0.36 \mathrm{~g}, 9.0 \mathrm{mmol}$ ) in anhydrous THF ( 90 mL ) cooled at $0{ }^{\circ} \mathrm{C}$ was added dropwise thiophenol $(0.72 \mathrm{~g}$, $6.6 \mathrm{mmol})$. After the addition was complete, the solution was warmed to rt and stirred for a further 30 min before methyl-2-bromopropionate $346(1.0 \mathrm{~g}, 6.0$ mmol ) was added. After 1 h at rt the reaction mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and quenched with water $(20 \mathrm{~mL})$. The aqueous layer was separated and extracted with ethyl acetate ( $3 \times 40 \mathrm{~mL}$ ). The organic extracts were combined, washed with brine ( 50 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give the crude thioether as a yellow oil. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, 15:1) afforded the thioether 347 ( $1.19 \mathrm{~g}, 98 \%$ ) a colourless oil.

## Methyl 2-methyl-3-oxo-2-(phenylsulfanyl)butanoate 348

To a solution of lithium bis(trimethylsilyl)amide ( 5.98 mL of a 1.0 M solution in THF, 5.98 mmol ) in anhydrous THF ( 6 mL ) cooled at $-78{ }^{\circ} \mathrm{C}$ was added a solution
of 347 ( $1.18 \mathrm{~g}, 5.98 \mathrm{mmol}$ ) in anhydrous THF ( 6 mL ). The solution was stirred for 30 min at $0{ }^{\circ} \mathrm{C}$ before being cooled to $-78{ }^{\circ} \mathrm{C}$. A solution of acetyl chloride $(0.45 \mathrm{~g}, 6.0 \mathrm{mmol})$ in anhydrous THF ( 6 mL ) was then added. The resulting mixture was stirred for 40 min at $0{ }^{\circ} \mathrm{C}$ before being quenched with a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(5 \mathrm{~mL})$. The aqueous layer was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 20 \mathrm{~mL})$. The organic extracts were combined, washed with water ( 10 mL ), a saturated aqueous solution of $\mathrm{NaHCO}_{3}(10 \mathrm{~mL})$ and brine (10 mL) then dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo to give the crude butanoate. Flash column chromatography on silica gel (petroleum ether - ethyl acetate, 15:1) afforded the butanoate 348 ( $1.14 \mathrm{~g}, 80 \%, 91 \% \mathrm{brsm}$ ) as a colourless oil.
$\mathrm{R}_{f}=0.29$ (petroleum ether - ethyl acetate, $4: 1$ ); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 7.43-7.30 (5H, m, CH-Ar), 3.79 (3H, s, CH3-C6), 2.36 (3H, s, CH3-C4), 1.50 (3H, s, $\left.\mathrm{CH}_{3}-\mathrm{C} 5\right)$; ${ }^{13} \mathrm{C}$ NMR (100 MHz, $\mathrm{CDCl}_{3}$ ) ס 199.5 (C-C3), 170.6 (C-C1), 137.1 (CH-Ar), 130.1 (CH-Ar), 129.3 (C-Ar), 129.1 (CH-Ar), 65.8 (C-C2), 53.4 ( $\left.\mathrm{CH}_{3}-\mathrm{C} 6\right), 26.2$ $\left(\mathrm{CH}_{3}-\mathrm{C} 4\right), 20.9\left(\mathrm{CH}_{3}-\mathrm{C} 5\right)$; HRMS $\left(\mathrm{Cl}, \mathrm{Me}_{3} \mathrm{CH}\right)[\mathrm{M}+\mathrm{H}]^{+}$for $\mathrm{C}_{12} \mathrm{H}_{15} \mathrm{O}_{3} \mathrm{~S}$ calcd 239.0743, found 239.0740, $\Delta-0.8 \mathrm{ppm}$; LRMS ( $\mathrm{CI}, \mathrm{Me}_{3} \mathrm{CH}$ ) m/z (intensity) 239.2 (100\%), 221.2 (18\%), 131.2 (33\%); IR $v_{\max } 1740,1711,974,869,753,693 \mathrm{~cm}^{-1}$.

## L-Phenylalanine methylamide $353^{112,129}$

To a suspension of L-phenylalanine $352(4.0 \mathrm{~g}, 24 \mathrm{mmol})$ in freshly distilled pyridine ( 120 mL ) at rt , was added dichlorodimethylsilane ( $3.4 \mathrm{~g}, 27 \mathrm{mmol}$ ) in one portion. During 2 min the mixture turned clear and methylamine gas ( $\approx 4 \mathrm{~g}$, 130 mmol ) was then bubbled through the reaction. The reaction mixture was stirred for 18 h at rt and then concentrated in vacuo. Flash column chromatography on silica gel $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}-\mathrm{MeOH}\right.$, gradient elution $100 \% \mathrm{CH}_{2} \mathrm{Cl}_{2} \rightarrow$ 3:2) afforded L-phenylalanine-methylamide 353 ( $2.8 \mathrm{~g}, 66 \%$ ) as a colourless solid.
$\mathrm{R}_{f}=0.73\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}-\mathrm{MeOH}, 3: 1\right)$; m.p. $66-68{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR (400 MHz, $\left.\mathrm{CDCl}_{3}\right)$ ס 7.31-7.21 (5H, m, CH-Ar), 3.60 (1H, dd, J = 9.5, 4.0 Hz, CH-C2), 3.29 ( 1 H , dd,

(1R,7R,6S,8R,9S,12E)-3-Ethoxy-6-isopropyl-13-methyl-15-oxatricyclo [6.6.1.0 ${ }^{2,7}$ ]pentadeca-2,12-dien-9-ol 378

To a flask containing the alcohol 372 ( $95 \mathrm{mg}, 0.21 \mathrm{mmol}$ ), DMAP ( 135 mg , 1.11 mmol ) and distilled triethylamine ( $561 \mathrm{mg}, 5.54 \mathrm{mmol}$ ) was added freshly distilled acetic anhydride ( $1.13 \mathrm{~g}, 11.1 \mathrm{mmol}$ ). The resulting solution was heated at $40{ }^{\circ} \mathrm{C}$ for 30 min , then cooled at $0{ }^{\circ} \mathrm{C}$ and quenched with a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(3 \mathrm{~mL})$ and $\mathrm{Et}_{2} \mathrm{O}(5 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 5 \mathrm{~mL})$. The organic extracts were combined, washed with brine $(5 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was filtered through a pad of silica gel (petroleum ether - ethyl acetate, 10:1 with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) to afford the crude acetate as a colourless oil. Without further purification, the crude acetate 377 was engaged to the next step.
A small freshly cut piece of potassium ( $\approx 100 \mathrm{mg}$ ) was added to a solution of recrystallised 18 -crown-6 ( $530 \mathrm{mg}, 2.00 \mathrm{mmol}$ ) in freshly distilled $t$-butylamine $(20 \mathrm{~mL})$ at rt . The mixture was sonicated and then stirred at the same temperature until a dark blue colour developed after which anhydrous THF ( 20 mL ) was then added. The crude acetate 377 in anhydrous THF ( 4 mL ) was added on reappearance of the blue colour at such a rate that the colour did not disappear for a long time. After addition of the substrate and reappearance of the blue colour, the excess potassium was destroyed by addition of absolute ethanol, neutralised by addition of a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}$ and diluted with $\mathrm{Et}_{2} \mathrm{O}(20 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 10 \mathrm{~mL})$. The organic extracts were combined, washed with brine $(20 \mathrm{~mL})$, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, filtered and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (petroleum ether - ethyl acetate, gradient elution $100: 1 \rightarrow 30: 1$ with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) to afford the alcohol 378 as a colourless oil ( $44 \mathrm{mg}, 65 \%$ over 2 steps).

[6.6.1.0 ${ }^{2,7}$ ]penta-deca-3,12-dien-9-ol 380

To a stirred solution of the ketone $358(44 \mathrm{mg}, 0.11 \mathrm{mmol})$ and $\mathrm{PhN}(\mathrm{Tf})_{2}(78 \mathrm{mg}$, 0.22 mmol ) in anhydrous THF ( 1.5 mL ) at $-78{ }^{\circ} \mathrm{C}$ was added $\mathrm{NaHMDS}(270 \mu \mathrm{~L}$ of a 1.0 M solution in THF, 0.27 mmol ) dropwise. The resulting solution was stirred at $-78{ }^{\circ} \mathrm{C}$ for 2 h then quenched with water ( 3 mL ) at $-78{ }^{\circ} \mathrm{C}$, allowed to warm to rt and diluted with $\mathrm{Et}_{2} \mathrm{O}(3 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 5 \mathrm{~mL})$. The organic extracts were combined washed with brine ( 5 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was filtered through a pad of silica gel (petroleum ether - ethyl acetate, 10:1) to afford crude enol triflate 379 that was used for the next step without further purification.

To a solution of the crude enol triflate 379 , $\mathrm{LiCl}(23 \mathrm{mg}, 0.54 \mathrm{mmol}$ ) and $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}(12 \mathrm{mg}, 11 \mu \mathrm{~mol})$ in anhydrous THF ( 10 mL ) was added dropwise $\mathrm{MeMgCl}(180 \mu \mathrm{~L}$ of a 3 M solution in THF, 0.54 mmol$)$. The reaction mixture was stirred at rt for 4 h and then quenched at $0{ }^{\circ} \mathrm{C}$ by the addition of a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(5 \mathrm{~mL})$. The reaction mixture was allowed to warm to rt and diluted with $\mathrm{Et}_{2} \mathrm{O}(5 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 5 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 5 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (petroleum ether - ethyl acetate, 100:1) to deliver the crude alkene 357 contaminated with traces of $\mathrm{PPh}_{3}$. Without further purification the crude alkene was used for the next step.

To a solution of the crude alkene 357 and $4 \AA$ molecular sieves in anhydrous THF ( 2 mL ) was added TBAF ( $220 \mu \mathrm{~L}$ of a 1 M solution in THF, 0.22 mmol ). The reaction mixture was stirred at rt for 5 h and then quenched by the addition of a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(1 \mathrm{~mL})$. The molecular sieves were removed by filtration and rinsed with ethyl acetate. The aqueous phase was separated and extracted with ethyl acetate ( $3 \times 5 \mathrm{~mL}$ ). The organic extracts were combined, washed with brine $(5 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (petroleum ether - ethyl acetate, gradient elution 100:1 $\rightarrow$ 20:1 $\rightarrow$ 10:1) to deliver the alcohol 380 ( $21 \mathrm{mg}, 68 \%$ over four steps) as a colourless oil.

To a solution of cladiella-6,11-dien-3-ol ( $3.0 \mathrm{mg}, 9.8 \mu \mathrm{~mol}$ ) in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(300 \mu \mathrm{~L})$ at $0^{\circ} \mathrm{C}$ was added freshly distilled acetic anhydride ( $11 \mathrm{mg}, 98 \mu \mathrm{~mol}$ ) and a solution of trimethylsilyl trifluoromethanesulfonate ( $10 \mu \mathrm{~L}$ of a $1 \mathrm{mg} / \mathrm{mL}$ solution in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 0.49 \mu \mathrm{~mol}$ ). The reaction mixture was stirred for 30 min at $0{ }^{\circ} \mathrm{C}$ then quenched by the addition of a saturated aqueous solution of $\mathrm{NaHCO}_{3}(1 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times$ 3 mL ). The organic extracts were combined, washed with brine ( 5 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (petroleum ether - ethyl acetate, 10:1) to deliver the tetracycle 382 ( $2.2 \mathrm{mg}, 81 \%$ ) as a colourless oil.
$\mathrm{R}_{f}=0.65$ (petroleum ether - ethyl acetate, $6: 1$ ); ${ }^{1} \mathrm{H} \mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 5.45$ (1H, br d, J = 5.4 Hz, CH-C12), 4.02-4.01 (1H, m, CH-C9), 3.85 (1H, s, CH-C2), 2.95-2.91 (1H, m, CH-C10), 2.42-2.28 (2H, m, CH-C1, CH2-C5), 2.21 (1H, dd, $\left.J=14.4,5.2 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 8\right), 1.92-1.82$ ( $4 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}-\mathrm{C} 4, \mathrm{CH}_{2}-\mathrm{C} 8, \mathrm{CH}_{2}-\mathrm{C} 13, \mathrm{CH}-\mathrm{C} 15$ ), 1.73-1.67 (1H, m, CH2-C13), $1.66\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 20\right), 1.54-1.33\left(5 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}-\mathrm{C} 4\right.$, $\left.\mathrm{CH}_{2}-\mathrm{C} 5, \mathrm{CH}_{2}-\mathrm{C} 6, \mathrm{CH}-\mathrm{C} 14\right), 1.31$ ( $3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 19$ ), 1.09 ( $3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 18$ ), 0.93 (3H, $\left.\mathrm{d}, \mathrm{J}=6.8 \mathrm{~Hz}, \mathrm{CH}_{3}-\mathrm{C} 16\right), 0.77\left(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=6.8 \mathrm{~Hz}, \mathrm{CH}_{3}-\mathrm{C} 17\right)$; ${ }^{13} \mathrm{C}$ NMR (125 MHz, $\left.\mathrm{CDCl}_{3}\right) \delta 133.7$ (C-C11), 121.2 (CH-C12), 91.7 (CH-C2), 81.4 (CH-C9), 75.9 (C-C3), 74.3 (C-C7), 48.3 ( $\mathrm{CH}-\mathrm{C} 10$ ), 48.2 ( $\left.\mathrm{CH}_{2}-\mathrm{C} 8\right), 42.1$ ( $\left.\mathrm{CH}-\mathrm{C} 1\right), 39.7\left(\mathrm{CH}_{2}-\mathrm{C} 6\right), 38.9$ (CH-C14), $36.3\left(\mathrm{CH}_{2}-\mathrm{C} 4\right), 35.8\left(\mathrm{CH}_{3}-\mathrm{C} 19\right), 28.4(\mathrm{CH}-\mathrm{C} 15), 28.2\left(\mathrm{CH}_{3}-\mathrm{C} 18\right), 22.6$ $\left(\mathrm{CH}_{3}-\mathrm{C} 20\right), 22.3\left(\mathrm{CH}_{2}-\mathrm{C} 13\right), 22.0\left(\mathrm{CH}_{3}-\mathrm{C} 16\right), 18.4\left(\mathrm{CH}_{2}-\mathrm{C} 5\right), 15.6\left(\mathrm{CH}_{3}-\mathrm{C} 17\right)$; IR $v_{\max }$ 2959, 2923, 1761, $1734 \mathrm{~cm}^{-1} ;[\alpha]^{25}{ }_{\mathrm{D}}+17.1\left(c=0.73, \mathrm{CHCl}_{3}\right)\left\{\mathrm{Lit}^{31}{ }^{31}[\alpha]_{\mathrm{D}}^{23}+19.0(\mathrm{c}\right.$ $\left.\left.=0.37, \mathrm{CHCl}_{3}\right)\right\}$.
(1R,2R,6R,7R, 8R,9S, 12E)-13-Methyl-3-methylidene-6-(propan-2-yl)-15oxatricyclo[6.6.1.0 ${ }^{2,7}$ ]pentadec-12-en-9-ol 384

To a flask containing the alcohol 372 ( $265 \mathrm{mg}, 590 \mu \mathrm{~mol}$ ), DMAP ( 359 mg , 2.94 mmol ) and distilled triethylamine ( $1.48 \mathrm{~g}, 14.7 \mathrm{mmol}$ ) was added freshly distilled acetic anhydride ( $3.00 \mathrm{~g}, 29.4 \mathrm{mmol}$ ). The resulting solution was heated at $40{ }^{\circ} \mathrm{C}$ for 30 min before being cooled at $0{ }^{\circ} \mathrm{C}$ and quenched with a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$ and $\mathrm{Et}_{2} \mathrm{O}(20 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 20 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 20 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was filtered through a pad of silica gel (petroleum ether ethyl acetate, $10: 1$ with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) to afford crude acetate 377 as a colourless oil which was used without further purification in the next step.

To a solution of the above crude acetate 377 in $\mathrm{THF}(30 \mathrm{~mL})$ was added 1 M HCl $(630 \mu \mathrm{~L}, 630 \mu \mathrm{~mol})$ and the solution was stirred at rt 1 h then diluted with $\mathrm{Et}_{2} \mathrm{O}$ $(30 \mathrm{~mL})$ and water $(30 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 20 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 30 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was filtered through a pad of silica gel (petroleum ether - ethyl acetate, 10:1) and the solvent removed in vacuo to deliver the crude ketone 386 which was used without further purification in to the next step.
To a solution of $\mathrm{Ph}_{3} \mathrm{PCH}_{3} \mathrm{Br}(1.13 \mathrm{~g}, 3.16 \mathrm{mmol})$ in anhydrous THF ( 10 mL ) at $0{ }^{\circ} \mathrm{C}$ was added dropwise NaHMDS ( 0.34 mL of a 1 M solution in THF, 0.34 mmol ). The resulting yellow reaction mixture was stirred for 1 h at rt . The above crude
ketone 386 in anhydrous THF ( 10 mL ) was added dropwise to the solution of ylide. The solution was stirred at reflux for 1 h and then cooled to rt before being quenched with a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$ and diluted with $\mathrm{Et}_{2} \mathrm{O}(20 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}$ $(2 \times 20 \mathrm{~mL})$. The organic extracts were combined, dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was filtered through a pad of silica gel (petroleum ether - ethyl acetate 10:1) and the solvent removed in vacuo to give the crude diene 385 which was used without further purification in the next step.
A small freshly cut piece of potassium ( $\approx 200 \mathrm{mg}$ ) was added to a solution of recrystallised 18 -crown-6 ( $780 \mathrm{mg}, 2.95 \mathrm{mmol}$ ) in freshly distilled $t$-butylamine ( 30 mL ) at rt. The mixture was sonicated and stirred at rt until a dark blue colour developed after which anhydrous THF ( 30 mL ) was added. The crude diene 385 in anhydrous THF ( 10 mL ) was added on reappearance of the blue colour at such a rate that the colour did not disappear for a long time. After addition of the substrate and reappearance of the blue colour, the excess potassium was destroyed by addition of absolute ethanol, neutralised by addition of a saturated aqueous solution of $\mathrm{NH}_{4} \mathrm{Cl}$ and diluted with $\mathrm{Et}_{2} \mathrm{O}(30 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 20 \mathrm{~mL})$. The organic extracts were combined washed with brine ( 20 mL ), dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$, filtered and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (petroleum ether - ethyl acetate, gradient elution 100:1 $\rightarrow 10: 1$ with $1 \% \mathrm{Et}_{3} \mathrm{~N}$ ) to afford the alcohol 384 as a colourless solid (81 $\mathrm{mg}, 47 \%$ for four steps).
$\mathrm{R}_{f}=0.58$ (petroleum ether - ethyl acetate, 2:1); m.p. 149-152 ${ }^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 5.33(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}-\mathrm{C} 6), 4.78\left(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=1.9 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 19\right), 4.72$ ( $1 \mathrm{H}, \mathrm{t}, J=1.9 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 19$ ), $4.03(1 \mathrm{H}, \mathrm{dd}, J=9.9,5.9 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 9), 3.63(1 \mathrm{H}, \mathrm{d}$, $J=9.2 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 2), 3.04(1 \mathrm{H}, \mathrm{ddd}, 9.2,8.2,6.5 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 3), 2.70(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=$ 9.9, $6.5 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 10$ ), 2.45 (1H, dd, $J=13.8,5.9 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 8$ ), 2.29 ( 1 H , dddd, $J=$ 12.3, 12.3, 12.3, 4.2 Hz, CH2-C5), 2.26 (1H, ddd, $J=13.5,3.2,3.2 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 12$ ), 2.24-2.16 (1H, m, CH2-C5), 2.16-2.10 (1H, m, CH2-C12), 2.05 ( $1 \mathrm{H}, \mathrm{d}, \mathrm{J}=13.8$ $\left.\mathrm{Hz}, \mathrm{CH}_{2}-\mathrm{C} 8\right), 2.01(1 \mathrm{H}, \mathrm{dd}, \mathrm{J}=11.8,6.5 \mathrm{~Hz}, \mathrm{CH}-\mathrm{C} 1), 1.95-1.85\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}-\mathrm{C} 4\right.$, $\mathrm{CH}-\mathrm{C} 15), 1.85\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 18\right), 1.79-1.71\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}-\mathrm{C} 4, \mathrm{CH}_{2}-\mathrm{C} 13\right)$, 1.41-1.32 (1H, m, CH-C14), 1.13 (1H, d, J = $6.5 \mathrm{~Hz}, \mathrm{OH}$ ), $1.02-0.98$ (1H, m, CH2-C13), 0.95 (3H, d, J = 6.9 Hz, CH3-C16), 0.74 (3H, d, J = $6.9 \mathrm{~Hz}, C_{3}-\mathrm{C} 17$ ); NMR (100 MHz,

(1R,2R,6R,7R,8R,9R,12E)-9,13-Dimethyl-3-methylidene-6-(propan-2-yl)-15oxatricyclo[6.6.1.0 ${ }^{2,7}$ ]pentadec-12-en-9-ol

To a solution of the alcohol $384(80 \mathrm{mg}, 0.27 \mathrm{mmol})$ in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(12 \mathrm{~mL})$ was added pyridine ( $87 \mathrm{mg}, 1.1 \mathrm{mmol}$ ) and Dess-Martin periodinane ( 175 mg , $410 \mu \mathrm{~mol})$ at rt . The reaction mixture was stirred at this temperature for 30 min before being quenched with a saturated aqueous solution of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ and $\mathrm{NaHCO}_{3}$ ( $5: 1,6 \mathrm{~mL}$ ). The mixture was diluted with $\mathrm{Et}_{2} \mathrm{O}(20 \mathrm{~mL})$ and stirred vigorously for 1 h . The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 10 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 10 mL ), dried ( $\mathrm{MgSO}_{4}$ ), filtered and concentrated in vacuo. The residue was filtered through a pad of silica gel (petroleum ether - ethyl acetate, 15:1) to afford crude ketone 387 which was used without further purification in the next step.

To a solution of the above crude ketone 387 in THF ( 10 mL ) was added $\mathrm{NaBF}_{4}$ ( $301 \mathrm{mg}, 2.75 \mathrm{mmol}$ ) at rt . The mixture was stirred at rt for 10 min and then cooled at $-78{ }^{\circ} \mathrm{C}$. MeLi ( 0.52 mL of a 1.6 M solution in THF, 0.83 mmol ) was added and the reaction mixture was stirred at $-78{ }^{\circ} \mathrm{C}$ for 30 min . The reaction was quenched with a saturated aqueous solution of $\mathrm{NaHCO}_{3}(5 \mathrm{~mL})$, diluted with $\mathrm{Et}_{2} \mathrm{O}(10 \mathrm{~mL})$ and allowed to warm to rt . The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 10 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 10 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The
residue was purified by flash column chromatography on silica gel ( $n$-hexane ethyl acetate, 20:1) to deliver the alcohol 383 ( $65 \mathrm{mg}, 78 \%$ over two steps) as a colourless solid.
 $\left.\mathrm{CDCl}_{3}\right) \delta 5.58(1 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{CH}-\mathrm{C} 6), 4.77\left(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=2.0 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 20\right), 4.70(1 \mathrm{H}, \mathrm{s}$, $\mathrm{CH}_{2}-\mathrm{C} 20$ ), 4.01 (1H, br s, CH-C9), 3.74 (1H, s, CH-C2), 2.69 (1H, br s, CH-C10), 2.45 (1H, dd, J = 13.8, $\left.5.4 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 8\right)$, 2.44-2.36 (1H, m, CH2-C5), 2.25 ( 1 H , $\left.J=12.9,3.4 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 12\right), 2.20-2.05\left(3 \mathrm{H}, \mathrm{m}, \mathrm{CH}-\mathrm{C} 1, \mathrm{CH}_{2}-\mathrm{C} 5, \mathrm{CH}_{2}-\mathrm{C} 12\right), 2.02$ ( $1 \mathrm{H}, \mathrm{d}, \mathrm{J}=13.8 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 8$ ), $1.87\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 19\right), 1.86-1.80(1 \mathrm{H}, \mathrm{m}, \mathrm{CH}-\mathrm{C} 15)$, 1.72 (1H, dddd, $\left.12.9,3.5,3.5,3.4 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 13\right), 1.70-1.63\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}-\mathrm{C} 4\right)$, 1.35-1.25 (2H, m, CH-C14, OH), 1.17 ( $3 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{CH}_{3}-\mathrm{C} 18$ ), 1.03 (1H, dddd, $\left.J=12.9,12.9,12.9,3.5 \mathrm{~Hz}, \mathrm{CH}_{2}-\mathrm{C} 13\right), 0.95\left(3 \mathrm{H}, \mathrm{d}, \mathrm{J}=6.9 \mathrm{~Hz}, \mathrm{CH}_{3}-\mathrm{C} 16\right), 0.75$ (3H, d, J = 6.9 Hz, CH3-C17); ${ }^{13} \mathrm{C}$ NMR (125 MHz, $\left.\mathrm{CDCl}_{3}\right) ~ \delta 146.8(\mathrm{C}-\mathrm{C} 11), 132.8$ (CH-C6), 124.8 (C-C7), 110.4 ( $\mathrm{CH}_{2}-\mathrm{C} 20$ ), 92.3 ( $\mathrm{CH}-\mathrm{C} 2$ ), 80.4 ( $\mathrm{CH}-\mathrm{C} 9$ ), 75.3 (C-C3), 48.1 (CH-C10), 46.3 ( $\mathrm{CH}-\mathrm{C} 1$ ), 42.7 ( $\mathrm{CH}-\mathrm{C} 14$ ), $39.0\left(\mathrm{CH}_{2}-\mathrm{C} 4\right), 38.7\left(\mathrm{CH}_{2}-\mathrm{C} 8\right), 31.5$ ( $\left.\mathrm{CH}_{2}-\mathrm{C} 12\right), 29.8\left(\mathrm{CH}_{3}-\mathrm{C} 18\right), 28.2(\mathrm{CH}-\mathrm{C} 15), 25.4\left(\mathrm{CH}_{2}-\mathrm{C} 13\right), 24.5\left(\mathrm{CH}_{2}-\mathrm{C} 5\right), 22.1$ $\left(\mathrm{CH}_{3}-\mathrm{C} 16\right), 20.6\left(\mathrm{CH}_{3}-\mathrm{C} 19\right), 15.5\left(\mathrm{CH}_{3}-\mathrm{C} 17\right)$; HRMS (EI) [M] ${ }^{+}$calcd for $\mathrm{C}_{20} \mathrm{H}_{32} \mathrm{O}_{3}$ 304.2404, found 304.2401, $\Delta-0.3 \mathrm{ppm}$; LRMS (EI) m/z (intensity) 304.3 (25\%), 286.3 (10\%), 243.2 (9\%), 219.2 (19\%), 179.1 (91\%), 59.1 (100\%); IR $v_{\max }$ 3427, 2957, 2929, 2914, 2874, 1643, 1448, $890 \mathrm{~cm}^{-1} ;[\alpha]^{26}{ }_{\mathrm{D}}-37.6$ (c = 1.00, $\mathrm{CHCl}_{3}$ ).

(-)-Sclerophytin A

To a solution of the alcohol $383(4.0 \mathrm{mg}, 13 \mu \mathrm{~mol})$ in a THF: $\mathrm{H}_{2} \mathrm{O}$ (1:1) mixture $(0.8 \mathrm{~mL})$ at $0{ }^{\circ} \mathrm{C}$ was added $\mathrm{NMO}\left(15 \mu \mathrm{~L}\right.$ of a $1.0 \mathrm{~g} / \mathrm{mL}$ solution in $\mathrm{H}_{2} \mathrm{O}$, $0.13 \mathrm{mmol})$ and $\mathrm{OsO}_{4}\left(1.7 \mu \mathrm{~L}\right.$ of a $4.0 \mathrm{wt} \%$ solution in $\left.\mathrm{H}_{2} \mathrm{O}, 0.26 \mu \mathrm{~mol}\right)$. The reaction mixture was stirred at $0{ }^{\circ} \mathrm{C}$ for 1 h and at rt for 1 h . The reaction was then quenched with a saturated aqueous solution of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(2 \mathrm{~mL})$, and the
mixture was stirred vigorously for 30 min before being diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (2 $\mathrm{mL})$. The aqueous phase was separated and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 3 \mathrm{~mL})$. The organic extracts were combined, washed with brine ( 3 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel ( $n$-hexane - ethyl acetate, 4:1) to deliver (-)sclerophytin A ( $2.6 \mathrm{mg}, 59 \%$ ) as colourless crystals.

(+)-Polyanthellin $\mathrm{A}^{8,13,31,36,127}$

To a flask containing (+)-deacetylpolyanthellin A (2.6 mg, $8.0 \mu \mathrm{~mol})$, DMAP ( $5.0 \mathrm{mg}, 40 \mu \mathrm{~mol}$ ) and distilled triethylamine ( $41 \mathrm{mg}, 0.40 \mathrm{mmol}$ ) was added freshly distilled acetic anhydride ( $44 \mathrm{mg}, 0.40 \mathrm{mmol}$ ). The resulting solution was stirred at rt for 1 h , then cooled at $0{ }^{\circ} \mathrm{C}$ and the reaction was quenched with a saturated aqueous solution of $\mathrm{NaHCO}_{3}(1 \mathrm{~mL})$ and $\mathrm{Et}_{2} \mathrm{O}(2 \mathrm{~mL})$. The aqueous phase was separated and extracted with $\mathrm{Et}_{2} \mathrm{O}(3 \times 2 \mathrm{~mL})$. The organic extracts were combined washed with brine $(2 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo. The residue was purified by flash column chromatography on silica gel (petroleum ether - ethyl acetate, 30:1) to afford (+)-polyanthellin A ( $1.6 \mathrm{mg}, 55 \%$ ) as a colourless oil.
