PREFACE

The investigations reported in this thesis had their basis in an investigation initiated by the Medical Women's Federation into factual knowledge of the menopause.

The author became interested in this subject as a member of the committee appointed to carry out the inquiry.

The investigations carried out and quoted in this thesis were carried out entirely by the author whilst practising as a partner in a busy general practice in the City of Glasgow.

The circumstances therefore demanded that this be purely a clinical inquiry, without any laboratory or other ancillary investigations.

ì

INTRODUCTION

1

In 1926 a sub-committee was appointed by the Council of the Medical Women's Federation for the purpose of investigating from the clinical aspect the phenomena associated with the climacteric. The data on which this report was based and published in 1933 were collected on 1220 questionnaire forms, each of which was completed by a medical woman as a result of a personal interview with the patient. The inquiry referred to women in whom five years or more had elapsed since the cessation of menses. Their ages when interviewed varied from 29 to 91 years. The subjects of the report were women of varying social status, rural and urban dwellers throughout Great Britain, understood to be in good health.

In 1954 a sub-committee was again appointed to conduct a similar survey, as it was thought that with improving social standards, the introduction and availability of hormone preparations, and possibly a more enlightened attitude towards the "critical years", the results of the

1933 study might not be applieable to women of the present day. Under the chairmanship of Dr. Mary Ecslemont, the members of the committee were Miss Josephine Barnes, Dr. Ima Gibson, Dr. Mona Macmaughton, Dr. Mary Pickford, Dr. Joan Taylor and the author. The Muirhead Trust agreed to sponsor the investigation, provided that a Scottish graduate was responsible for the survey. Accordingly, the author was granted control of the work under the surveillance of the Steering committee.

The aims of the committee included assessments of the frequency of symptoms (particularly those necessitating medical advice), the working capacity of the menopausal woman and the effect of various factors peculiar to a woman's pre-menopausal life. The form of the questionnaire was agreed and a copy may be seen in the appendix (p. 233).

It was realised that a major fault of the original study was the possible long lapse of time between actual consection of menses and the time of interview. The present questionnaize was therefore confined to women whose menopause had occurred less than five years before, but more than two years previously.

6,

Women general practitioners throughout the country were invited to complete the questionnaire, as it was appreciated that the family doctor would have a more random sample of patients than the specialist. Five hundred completed forms were forwarded to the author from this source.

Working independently in Glasgow, the author amassed a further 500 forms and this group became the basis of the thesis. Of these women, 450 had experienced a natural menopause, and 50 women had undergone an artificial induction of the menopause.

Dr. Peter McKinlay of the Department of Health in Edinburgh had kindly agreed to undertake the statistical survey of both the author's group of 500 women and the further group combining the countrywide ceries with this series. The analysis of the latter group of 1000 menopausal women will be published in a medical journal.

Subsequent to Dr. McKinlay's retirement, his successor Dr. Alwyn Smith kindly offered his advice and help. This was greatly appreciated.

MENSPRUATION AND THE MENOPAUSE

.

.

.

.

,

THROUGH THE AGES.

MENSPRUATION

The occurrence of menses has occupied minds of philosophers and physicians since the boginning of time. NAPIER (1897), CRAWFURD (1915) and NOVAK (1931) enumerate some of the many theories.

Pythagorus (540 B.C.) referred to menstrual flow as a "froth" of the blood, maintaining that it was superfluous to the body; Hippocrates (400 B.C.) favoured a theory of uterine congestion, the flow being considered a sequel of plethora or congestion (attributed to the upright posture of the human race), with simultaneous purgation and self purification. The very name given by the Greeks to the process of menstruation ("catharsis") is indicative of this belief in the cleansing action of the menstrual flow.

Aristotle (384-322 B.C.) and Erasistratus (c. 260 B.C.) considered that monstruction was dependent on the phases of the moon - the so-called "lunar theory". Galen (23-79 A.D.) repudiated this influence of the astral bodies and supported the mechanical theory of plothors favoured by Hippocrates.

Pliny (23-79 A.D.) spoke of the menstrual flow as a "fatal poison" which would contaminate anything with which it came in contact. He believed that even the odour of the flow would make plants wither and flowers die. This theory had a practical application in Cappadocia, where menstrual women were sent to walk through the middle of fields infested with multitudes of cantharides and the vermin fell from the ears of corn, "but this was not done at sunrise for fear of the erop drying up".

Mosaic law persistently refers to the uncleanliness of the menstruating woman which lasted for seven days "at the end of which time she sacrificed turtle doves as a burnt offering". A "menstruous woman" of Biblical scriptures was an outcast to her tribe and family. This attitude even had medical support in 1878 when a correspondent to the British Medical Journal queried the wisdom of a woman curing hams at the time of her menstruation. The reply voiced the vory certain opinion that "the meat will be tainted if cured by a

woman at the catamonial poriod. Whatever the rationals, I can speak positively of the fact".

Even in this propent century OXLER (1950), referring to the "sensitivity" of wine, tells how no woman is ever allowed to "enter the <u>cave</u> and draw wine during her monthly periods" in the Dordogne valley of France. More sinister is the story told by CRAWFURD (1915) of the Australian who killed his wife "because she had lain on my blanket while she monstruated". The husband is reputed to have died of fright in a fortnight.

Little wondor that the 20th contury woman talks of hor #1.11messes" or "the curse".

In the 17th and 18th conturies, De Graaf Diemerbrock and Hoffman considered a formentation process was responsible, the formentation of the circulating blood being likened to the formentation of a red wine with the resultant overloading of the vascular system and a consequent relief with menstrual flow.

Roussell and his followers in the 19th century advocated a theory of heredity. They assumed that monstruction was

not an inherent function but one acquired by custom or heredity. Conflicting opinions at that time favoured "the menstrual nerve" theory of Johnstone, and the idea presented by Martin and Collim that a nervous centre located in the lumbar region of the spinal cord had a controlling effect.

The beginning of modern knowledge of the subject may be traced to the demonstration in the ovary of the Graafian follicle in 1665 by De Graaf. It was not until one and a half conturies later that De Baer demonstrated the presence of ove within the follicles, and in 1832 Negrier suggested that the ovary was in some way associated with the occurrence of menstruation. In 1840, Gendrin and Raciborsky asserted the new known to be fallacious interdependence of menstruation and ovulation.

By 1930, a wealth of literature had been published on the field of hormone research. In surveys of these works, DODDS (1932) and SCHOELLER (1933) cite the pioneer work of Allen and Doisy who were the first to demonstrate the activity of the overian extracts. They injected subcutaneously an alcoholic extract of the overy into a castrated mouse and demonstrated the restoration of cyclical changes. Working independently, Butenandt, the German worker, isolated the active principle of the follicular hormone from the urine of pregnant women. It was then possible for a pure and accurately standardised form of cestrin to be marketed. In 1929, Corner isolated progesterone (the corpus luteum hormone) and it could then be appreciated that the ripening follicle of the ovary produced a group of closely related compounds or cestrogens associated with the development of the secondary sex organs of the female, and when the follicle became modified to form a corpus luteum, the luteal hormone or progesterone (excreted in the inactive form of prognandiol) stimulated the uterus to prepare a decidua suitable for nidation of an ovum.

Yet a further stimulus was added to the picture by the work of Ascheim and Zondeck. They showed that hypophysectomy in rate resulted in atrophy of the ovaries and suppression of cestrus. These sequelae were prevented by the grafting of the anterior pituitary gland into the animals so treated. Snith and Engle simultaneously showed that transplantation of

the anterior pitultary gland caused premature puberty with development of cestrus and luteinization of the ovaries in immature animals.

This establishment of the role of the anterior pituitary in the hormonal control of the body along with rapid development in the field of the ovarian hormones revolutionised the comprehension of female sex physiology in the early thirties.

THE LIFE OF THE OVARY

HERTIG (1944) states that the "human female is endowed at birth with a certain overian capital, namely the primerdial ova." He maintains that there are no new additions to such capital by way of cogenesis, either from the germinal opithelium or any other structures of the overy. Thus the ageing of the overy in one sense begins at birth and continues through life. Editewise NOVAK (1944) stated that long before menstrual function begins, costrogen is produced from the overy by follieles which mature to varying degrees.

With the advent of puberty, the complementary action of the overy and the pituitary glands is activated and initiated by the follicular stimulating hormone of the pituitary which cauces maturation of a series of overien follicles, one of which will develop more fully than the others and ovulate. The luteinizing hormone (LH) acts with the FSH to premote costrogen production and it is the balance of these two genedotrophic hormones that causes rupture of the follicle and is essential to the formation of the corpus luteum. Eventually the costrogen

concentration depresses FSH and encourages its replacement by more LH and the lutectrophic hormone (LEH): the LEH stimulates the already formed corpus luteum to secrete progesterene and eventually the cestrogen/progesterene ratio brings about constition of LH and LEH production. There is subsequent degeneration of the corpus luteum with lowering of cestrogen levels and "crusbling necrects" of the endemstrium. The FSH then recurse a further cycle. It is quite plain that this "see-saw" action of the pituitary and overy is a delicately balanced hormonal interplay.

As life progresses through the ago of thirty to forty, the agoing of the every takes place in "an orderly and progressive fashion with gradual less of the primordial eve and their follicular phases" (HERVIG, 1944). The change is gradual and takes place over months or even years. PRATT (1950) claims that by careful dissection of the whole everies, one finds that "during the fourth and fifth decades it is possible to show a gradual decline in the number of follicles."

Consequently, as the months or years progress, there is a decreased production of the costrogens and the overy becomes refractory to the genedotrophic stimulation of the pituitary, and the menopause (or constion of menes) occurs.

The ovary becomes conescent, and as the post-monopausal years progress, the ovary becomes half its pro-monopausal size and assumes a white wrinkled external appearance.

.

ı.

THE MENOPAUSE AND CLIMACTERIC

The menopause literally means the cessation of monstruation. It is an event unique to the human primate. The term "climactoric" derived from the Greek and meaning the rung of a ladder. is a comprehensive term referring to a transitional phase from the reproductive or menacmic period to the post-menacaic phase. More recently the term "hypoovarianism" has been favoured by clinicians. Many authors condemn the synonymous use of the terms "menopause" and "climactoric". Indeed, the former is an isolated incident The phrase "menopausal woman" is used in the climacteric. in later pages, when the woman has ceased menstruating and is "in the climacteric".

The protean symptoms of the "critical age" are anticipated by many women and few regard it as naively or unconcernedly as the adolescent does her menarche. LANGDON-BROWN (1935) refers to the elimacteric as the "running down of a clock that has been ceaselessly going". Folklore would seem to have set an alarm.

William Hunter states that the climacteric year or years of crises of the ancient astrologers were the seventh and ninth and their multiples, with the odd numbers three, five, seven and nine. These were described as critical periods in life, which were under the influence of malevolent and malicious Saturn, the planet of ill omen. The ages of 45 (5 times 9) and 49 (7 times 7) were approached with foreboding of evil, and the age of 63 (7 times 9) was looked upon as the grand climacteric which few outlived.

Ignorance and superstition die hard. The sudden cessation or irregularity of flow alert women in their fourth or fifth decade to the imminence of the climacteric. Indeed the only true symptom common to them all is termination of menses. Some authors claim that this gives many women a feeling of relief that the years of childbearing and pregnancies have passed. In Richard II, Shakespeare alludes to the cessation of childbearing as being coincident with the departure of menses, although not with the same happy note:

> "Have we more sons, or are we like to have, Is not my teeming date drunk up with time And wilt thou pluck my fair son from mine eye And rob me of a happy mother's name."

It is generally accepted that after one year's absolute amenorrhoea, any bleeding must be regarded as pathological. It is of interest to note that women who were confined to prisoner-of-war camps in Europe and in the Far East during the last war and subjected to a restricted dist experienced 48 or 24 months, amenorrhoea with subsequent return of monstrual activity on their return to normal life. MAPIER (1897) observed that in Esquimeux women there is a suspension of menstruation during the dark and prionged winter.

The irregular bleeding that may occur at the climacteric is explained by HAMBLEN (1945) as an cestrogenic bleeding. As ovulation and corpus luteum formation fail to take place, the cyclic influence of progesterone is no longer capable of modifying the pituitary function. The ovaries, however, may continue to respond to the follicular stimulating hormone and bleeding will occur with critical declines in the cestrogenic levels.

There is varying opinion as to whother there is true hyperactivity of the pituitary at the menopause or not.

The amount of genedotrophins in a monstrual woman is detected in small quantities. It is found in either the

blood or the urine, and it varies with the phase of the menstrual cycle and the circulating cestrogen. In the menopausal woman it is present in greater quantity and is a sure sign that the monopause has been reached. In later years, the amount of genadotrophins is small, an indication that the menopause has passed.

The theory that the increase of genadotrophins found at the menopause is in reality a false reading due to the failure of the ovary to utilise the genadotrophic hormone is disproved by the work of Severinghaus and Hamblen.

SEVERINGHAUS (1944) studied the pituitary gland in women of all ages, and stated that the anterior lobe of the hypophysis in the post-menopausal woman is hyperactive in production and release of its secretions. This view was supported by HAMBLEN (1945) who claimed that the action of the pituitary became uniphasic and primarily follicular stimulating in character. Histological examination of the hypophysis in castrated women showed hyperactivity with an increase in the cosinophils. Yet, similar examination of the gland after a normal menopause shows no increase in the cosinophil content and a decrease in the weight of the gland.

MONTGOMERY (1945) claims that the excess of gonadotrophins is the cause of many of the menopausal symptoms because of the direct relationship of the hypophysis on the other ductless glands, such as the thyroid, adrenal and pancreas.

LAWRENCE and MOULIN (1941) found that 81% of women with excess urinary gonadotrophins had menopausal symptoms as opposed to only 15% women with negative tests for excess gonadotrophins and symptoms. HURXTHALL (1951), however, repudiates the hyperactivity of the hypophysis as a cause of symptoms, by quoting the ovarian agenesis syndrome where the ovaries never function. The gonadotrophins are in excess and yet the symptoms are "conspicuous by their absence".

HELLER, FARNEY and MYERS (1944) observed 27 castrated women at intervals with particular reference to the urinary genadotrophins, vaginal smears and symptome. The first to alter was the urinary genadotrophin titre which showed a "significant rise" as early as the sixth day in 58% women, and at the tenth post-operative day in 86% of cases. At the end of one month, 100% of the cases exhibited a significant rise.

Retrogression of the vaginal cytology occurred in most cases, but could not be correlated to the date of onset of symptoms or rise in urinary gonadotrophic titre level. They also claimed that four patients whose uninary gonadotrophic titre had been high pre-operatively, and whose genital organs showed a degree of atrophy, developed menopausal symptoms as a result of castration. This suggested to them that the atrophic overy continues to secrete small amounts of cestrogens after the menopause. This view is supported by McLAREN (1941) who investigated the pH, bacteriology, cell smears and histology of the post-He concluded: "It will be seen that the monopausal vagina. usual statement that after the menopause the genital tract undergoes atrophy, and the vaginal mucosa becomes thin, is far from representing the true state of affairs. In fact. histological exemination of the vagina demonstrates that 65% of the appearances were normal, and this corresponded roughly to the findings of Grade III smears in 78% women". These findings afforded confirmatory evidence of overian activity after the menopause. It is of interest to note here that the work of OSMOND-CLARKE and MURRAY (1958) suggested the

value of vaginal smears in assessing the response to treatment and management of the menopause,

HAMBLEN (1945) referred to the advenal glands as the gonads of the aged and claimed that the duration and severity of symptoms among other things might depend on the cortical response which tonds to stabilise the endocrine system. The adronal steroids have a similar structure chemically to the cestrogens and it may be that they substitute for the lowered cestrogens in an effort to depress and stabilise the relatively uninhibited pitultary, It may be too that the medulla of the advenal is also affected by a stimulation and this could explain the instability of the vasomotor system FREED (1950) claimed that the of the climactoric woman. relative over-propondorance of androgens might be responsible for the increase of hair growth seen occasionally in the monopausal woman, and the loss stanificant decline in fomale charactoristics. Experimentally it has been shown that there is a transient increase in the urinary 17-keto steroids during the climacteric or subsequent to copherectomy.

WERNER (1953) claims that the picture is further complicated by the effect of the endocrine glands on the central nervous system, including the hypothalamus and the autonomic nervous system. The latter controls the emotions, to a great extent the sense of well-being, cardiac and respiratory rates, chemical balance of body tissues and digestion. Thus, Werner concluded, some of the objective symptoms might be attributed to an imbalance of the autonomic nervous system.

Other factors which may control symptomatology of the climactoric will be studied later. Suffice it to say that the causation of menopausal symptoms remains ill understood.

REVIEW OF TREATMENT OF THE MENOPAUSE

Prior to the introduction of hormone therapy, the menopausal woman was advised to pay attention to diet, physical exercise and clothing. Indeed this advice may still be pertiment. The doctrine of cobriety in all things was considered essential. Hot foot baths, with or without mustard, in the evenings, cold sponge baths in the mornings, vaginal douching in married women, heavy Jacger woollen underwear and shoulder braces to support the weight of the petticoats, were but a few of the ninetsenth century Sexual excess was considered harmful and was remedies. thought to be a cause of menorrhegie. The drugs fevoured were bromide, valerian and musk. This sodation therapy was considered the sheet anchor of treatment.

Hormonal therapy is said to have been used first in the Landau Clinic in Berlin in 1896. "Natural ovary" was administered to women in the form of two sheep's ovaries daily. The fresh gland was obtained and finely chopped, and taken either in a bouillon or wrapped in a piece of

52*

unleavened bread and swallowed as a pill. Women objected to taking ovary in this form, and ovarine or cophorine was considered the drug of choice. This consisted of ovary (dried and powdered) from cows, mares or ewes during the time of their full sexual activity. The powder was given in a cachet in a dose of 0.125 gramme three times daily. Results from this therapy were said to be most favourable after castration, giving relief particularly to hot flushes. Modern writers condemn whole ovary therapy, caying that it is inert physiologically. BUXTON (1951) claims that by its use the profession is unconsciously using a "let of psychotherapy".

In 1938, Dodds and his co-workers synthesised diethylstilboestrol, and this was released for general use in the following year. Hexcestrol and diencestrol followed in 1940 and 1942. The advent of these cheaper synthetic products was viewed with caution by the medical profession, as indeed is any type of hormonal therapy. There is still reluctance to use stilboestrol, possibly because of the sequelae to prolonged treatment or unnecessarily heavy desage used in the early days of therapy. One of the dangers to

which the modern clinician is alerted is that very large doses of cestrogenic hormonos will induce the development of malignant tumours in susceptible animals. No evidence has been produced to show that cestrogenic therapy can induce malignant disease in the human.

A great deal of experimental work has been done to compare the efficiency and potency of the many natural and synthetic cestrogens on the market. As a result of these investigations one has a wide choice of material. Administration can be oral, parenteral or by implantation in the tissues. It is claimed without adequate proof that the natural cestrogens give a sense of well-being that is not experienced by the use of the synthetic hormones. The latter may give rise to unpleasant side effects, particularly nausee or vomiting, and may cause menorrhagia if given in too high a dosage or over a prolonged period.

The rational use of hormone therapy should obviously be considered in terms of costrogen replacement, for it is the lack of this substance which is deemed responsible for the instability of the menopause. Not, it must be remembered that the hormonal therapy at this time is

ľ

prolonging the process of cestrogen depletion through which the patient is passing. The aim of therapy, therefore, must be "gradually to reduce the amount of available cestrogen, so that the patient is eased into a state of complete cestrogen depletion rather than having her thrust into it" (MALLESON, 1956).

MONTGOMERY (1945) and JEFFCOATE (1960) consider that the relief of symptoms given by oostrogen thorapy may well be due to suppression of the genadotrophic hormones. Possibly this depressant effect may be reflected on the other endocrine glands, including the thyroid and adrenals, and so interfere further with the endocrine balance. For this reason, Montgemery condemns unnecessary and prolonged hormonal therapy, querying particularly the wisdom of its use during the irregular bleeding common to many women at the climactoric; as HAMBLEN (1945) has pointed out, this is often associated with high controgenic levels.

It is the wise physician who uses only one or two preparations known to him, and on which he can rely.

Synthetic stilboostrol is most used in this country, possibly due to its low price, combined with its efficacy

and ease of administration. The possible disadvantage of inducing nausea is shared by the other synthetic products hexcestrol and dincestrol. Ethinyl cestradiol, which is less liable to cause side effects, is 20 or 25 times more potent than stilboestrol, but MALLESON (1956) claims that it is "unnecessarily strong" for treatment in the climacteric, and caution should be exercised in its use.

Oestradiol benzoate given intramuscularly is rarely used in therapy of the menopause.

In America particularly, the use of implanted cestradiol pellets is advocated by some clinicians in an induced menopause, particularly in a young woman. It is favoured where parenteral or oral medication has failed, or is given at the time of castration. It has the effect of a gradually diminishing dosage over a period of 5 to 8 months, depending on the potency of the pellets. GREENBLATT (1952) states that the absorption is greatest during the first month (about 35%) and this gradually diminishes over a period of 150 to 240 days. PERLOFF (1949) advocates this treatment only at the time of operation and found that the only untoward reaction was an evanescent breast pain.

The use of androgens in therapy has been suggested in the past few years. As with costrogen therapy, their depreseant effect on the output of the anterior pitultary is the rationale of treatment. The androgens may be given intramuscularly or, more acceptably, orally, and have been marketed in sublingual tablets (methyl testosterone) and even as multihormonal tablets. JEFFCOATE (1960) finds their main advantage is absence of stimulation of the female secondary sex organs. with no possible complication of uterino bleeding. Furthermore, he states that they give a sonse of well-being, eliminate depression and increase libido. They are however expensive and he cautions their use because of risk of virilism. HUNTER (1953) found the risk of masculinisation slight if the drug is given in supervised and controlled dosages. FINGER (1952) advocates the use of the androgens where it is desirable to avoid cestrogen therapy:

- in patients who present monopausal symptoms and have monorrhagia;
- 2. in carcinoma of the breast or reproductive organs;
- 3. in patients who have had a cyclomastopathy;

4. for menopausal patients in whom costrogens induce excessive bleeding.

The use of Vitamin E in its synthetic form of alphatocopherol is claimed to be a useful form of treatment by some authors. The rationale of treatment is not clearly established, and McLAREN (1949) feels that the rationale of its use will remain obscure until the true cause of menopausal flushings is substantiated. It is an expensive preparation, but because of the absence of side effects, it may be valuable in patients who cannot tolerate the oestrogens, or who have irregular bleeding. Like the androgens, it would not stimulate potential cancer sites.

The variety of menopausal symptoms must be dealt with individually as they are presented and every author on the subject of treatment of the climacteric emphasises that reassurance or sedation may well suffice. JEFFCOATE (1960) concludes an article on the use of available hormonal drugs by stating that only in a "minority of carefully selected" cases is there any justification for giving therapy hormonal or otherwise - for the "flushes and tantrums of the climacteric". Publication of this statement invited

some hard-hitting replies, one correspondent stating that he was unsympathetic. The succeeding pages may help to unravel a vexed question.

MATERIAL AND METHODS

e

Since the author is a partner in general practice in Glasgow, the subjects in this report are of necessity city dwellers, and the data discussed hereafter can only be referable to women of a large industrial city.

The practice comprises approximately 4,500 patients, and is situated in the west of the city, extending from the once elegant Georgian terraced houses of Hillhead to the large Knightswood housing scheme.

The files of the practice were checked, and the names of all female patients between the ages of 40 and 60 were abstracted. All these women were visited at their homes or seen in the surgery by the author and the age of menopause ascertained. If this had occurred more than two years and less than five years before, a questionnaire was completed. In 1957, three years after the survey was initiated, 225 women came within the desired group. At the outset of the work, it was realised that the practice could not furnish 500 subjects required by the survey, within the time schedule set by the author, and the physicians and surgeons of the

ł

ł

Glasgow Royal Infirmary kindly allowed the author to visit the wards and interview patients. By 1958, 450 patients in all had been interviewed and this number forms the basis of the survey on the normal menopause. The 225 patients seen in the Infirmary were hospitalised for reasons such as hernia, injury or investigation; no gynaecological ward was visited, and no "seriously 111" patient was interviewed. Table I (p. 37) gives the diagnosis abstracted from the case sheet at the time of interview. It is hoped to compare the practice and hospital groups in symptomatology and other features. Only one woman refused to co-operate - the Matron's maid, who was hospitalised for a minor complaint. No doubt she recognised an alien figure in a white coat. The majority of women welcomed the interest in their menstrual history and The question on libido was included in the climactoric. questionnaire after a great deal of deliberation on the part of the stoering committee. In several households the question was received with obvious relief by women who "didn't like" to mention their despair of a distressing frigidity with ensuing domestic upset, or an increased "desire" which caused similar misundorstanding and embarrassment in the household.

TABLE 1 : 225 CASES INTERVIEWED IN GLASGOW ROYAL INFIRMARY

REASON FOR ADMISSION TO HOSPITAL

Surgical Wards

Medical Wards

This is a subject rarely raised in a general practitioner's surgery, unless the patient hersolf mentions it, and yet it may play an important part in and influence the domestic and social life of many middle aged women.

In addition to the 450 normal menopausal women, a further group of 50 patients who had undergone castration was questioned. Again, some were in the practice and some in hospital. If the latter, the hospital where the operation had occurred, or where therapy had been given, was contacted, and the surgeon in charge kindly forwarded details of pathology and treatment. Table 2 reveals the source of material of all patients.

| · · · · · | Normal Monopauso | Artificially induced Menopauso |

| | | | | | |

38,

The time taken to complete each questionnaire varied with the interest and verbosity of the subject (and occasionally of the author). The only practical aspect of the survey was the recording of the blood pressure. A great deal of interest has been focussed on "hypertension of the menopause" and it was considered of value to include it in this survey. The blood pressure reading was taken at the end of the interview, when the patient was at ease. seated or lying in bed. A mercury column sphygmomanometer was used on every occasion, and the silk cuff applied in such a way that the rubber compression bag was squarely above the brachial artery, about one inch above the elbow The first loud regular beat was taken as the oroase. systolic pressure and the diastolic was taken at a point when a distinct beat changed to a softer note.

When the 500 questionnaires were completed, tables were prepared and data abstracted. The statistical department of the Department of Health in Edinburgh helped with this task and Dr. Alwyn Smith commented on the final tables.

THE INVESTIGATION

.

THE NORMAL MENOPAUSE

.

;

The Age of the Menopause

In the 450 patients who had undergone a natural menopause, the average age at absolute cessation of menses was found to be 48.73 years. Of the hospital cases, the average was 48.58 and in the practice group, 48.88 years. The extreme ages were found to be 38 years and 57 years. Table 3 illustrates the age distribution.

| Age Group of Patient | Age of Patient | Number of Cases | Number and % of Womon within Age Group |
|----------------------------|----------------------------------------|---------------------------------------------|----------------------------------------------|
| -40 | 38 39 40 | 2 3 5 | 10 (2.2%) |
| 41-45 | 41 42 43 44 45 | 5 3 8 19 28 | 63 (14%) |
| 46-50 | 46 47 48 49 50 | 27 48 41 51 71 | 238 (52.9%) |
| 50+ | 51 52 53 54 55 56 57 | 51 46 22 1 2 3 3 2 | 139 (30.9%) |

TABLE 3 : DISTRIBUTION OF AGE OF MENOPAUSE IN 450 WOMEN

In the Appendix may be seen Table 3A illustrating the age distribution in both the hospital and practice groups.

The age of cessation of menses quoted by many authors in papers studying the climacteric over the past 20-30 years is 47 years. Statistical proof of this figure is not easily found. NOVAK (1931) quotes Webster as saying: "In temperate countries, it takes place in about 50% women between 45 and 50, in 25% between 40 and 45, in 12.5% between 35 and 40 and in 12.5% between 50 and 55."

MCLAREN (1941) in a series of 61 cases found the average age of menopause to be 45.3 and the MEDICAL WOMEN'S FEDERATION (1933) in a series of 1220 cases found an average of 46.4 years.

Table 4 illustrates a trend in the last 15 years to a higher incidence of cessation of menses in the 51+ age group. A possible interpretation of this could be that cestrogen therapy may have been given, and this would prolong actual cessation. As far as the practice group of patients is concerned, no hormonal therapy was given to any patient until a year of amenorrhoea had persisted.

In BACKMANN'S (1947) study of the literature he found that an analysis of early investigations warrants the statement that the menopause probably began at the age of about 40 years in ancient times, at the age of about 45 years in the period 1500-1830 and newadays at 48 years. Thus he states that the menopause has been retarded by about 3 years in the last century. Is this a consequence of the "social revolution" or may factors in a weman's life be responsible? These latter questions will now be discussed in relation to the age of the menopause.

The Age of Puberty as it may affect the Age of Menopause

In 450 women, the average age of puberty was found to be 14.18 years. The hospital group presented an average of 14.13 and the practice group 14.24 years. Table 5A in the Appendix illustrates the age distribution in the two groups. The extreme ages in all women interviewed were 10 and 19 years. Thus, with an average age of menopause of 48.73 and of puberty of 14.18, the average period of reproduction was 34.5 years.

Table 5 itemises the age of onset of mensos.

| Age at Onset of Menses | No. of Women | Average Age |
|----------------------------------------------------------|--------------------------------------------------------|-------------|
| 10 11 12 13 14 15 16 17 18 19 | 2 18 53 58 138 90 59 20 7 5 | 14.18 |

TABLE 5 : AGE OF ONSET OF MENSES IN 450 WOMEN

In biblical days, the age of puberty was considered from a legal standpoint as 12 years and a day - as a girl then "presented signs of maidenhood." In his survey of the literature BACKMANN (1947) found evidence that puberty occurred in ancient times, and for the most part in mediaeval times also, at the age of 14 years. In Europe, he found an average of 14.6 years in the present century.

The older writers were of the opinion that an early puberty favoured an early menopause, but later writers expressed the view that an early puberty was more likely to be followed by a late menopause (BACKMANN).

In an analysis of cases, SANES (1918) confirms "in a general way" that an abnormally early and abnormally late puberty favour an early menopause (although some of his cases of very early puberty reached an extremely late menopause).

Table 6 shows that in this series the difference in mean age at the menopause at different puberal ages was statistically insignificant. This confirms the findings of the M.W.F. (1933) and KAUPPINEN (1949). What can be gained from the statistics however is an approclation of the longer reproductive period in those who have an early menarche. Similarly, the later the puberty, the shorter is the reproductive period.

Pre-menstrual Tension as it may affect the Age of Menopeuse

The syndrome of pro-menstrual tension has long been acknowledged, but its cause remains ill-understood. MALLESON (1953) talks of a "negative state" balance or a state of "strange endogenous misery" in women, demonstrable in some for the few days prior to the onset of menses, which she claims is induced by hormonal imbalance. This phase of hormonal instability may be comparable to that present at the time of the menopause with its ensuing upsets.

Ill-understood as the syndrome may be, three factors appear to form the basis of pro-menstrual tension:

- 1. Imbalance of hormones
- 2. Emotional factors
- 3. Faulty salt metabolism.

CRAIG (1953) emphasises the emotional factor as the cause, in his survey, and says: "Many feel the whole syndrome is essentially psychogenic." MALLESON (1953), stressing the possible role of hormonal imbalance, asserts that, after ovulation, the changing ratio of cestrogen and progesterone at some point is the cause of the discomfort. APPLEBY (1960) cites the investigations of Geenhill, Freed and Sweeney, who demonstrated increase of weight and occasional actual oedema in the few days prior to menstruation. In a study of selected cases in his general practice, APPLEBY found that relief from pre-menstrual tension was given in one half of his patients with the sedative meprobamate ("Equanil"), in one third with the diuretic chlorothiazide ("Saluric") and in one fifth with progesterone derivatives.

In this series, each patient was asked if she had experienced any headache, vertigo, irritability or general malaise in the few days before menses. If the answer was in the affirmative, she was then asked how severe or incapacitating these symptoms were. If more than one symptom was present or if a single symptom was reckoned to be incapacitating, the patient was classified as "severe."

It is interesting to note that in spite of the increasing appreciation of this syndrome, 75% of patients in this series had no complaint of pre-menstrual tension. This is not in accord with the figures quoted by APPLEBY (1960) in his survey which gives varying incidences of 95% (Pennington), 55% (Appleby) and 36% (Bickers and Woods).

The occurrence of pre-menstrual tension did not vary in incidence, contrasting the hospital and practice groups (as can be seen in Table 7A in the Appendix) and Table 7 shows that no relationship was found between the incidence of premenstrual tension and the age of menopause.

| Pro-monstrual Tonsion | No. of Cases | % of Cases | Average Age Menopause |
|--------------------------|-----------------|---------------|--------------------------|
| Absont | 339 | 75•3 | 48.8 |
| Slight | 88 | 19.6 | 48.6 |
| Sovero | 23 | 5.1 | 48.05 |
| Total | 450 | 100.0 | 48.7 |

TABLE 7 : COMPARING THE INCIDENCE OF PRE-MENSTRUAL TENSION AND THE AGE OF MENOPAUSE

Dysmonorrhoea as it may affect the Age of Menopause

Dysmonorrhoea, by which is meant lower abdominal pain experienced at or near the menstrual period, has been a recognised entity since 1500 B.C., and had recognised treatment at the time of Soranus (2nd Century B.C.).

MOON (1950) states: "It would require not only knowledge of the anatomy, physiology and pathology of menstruation but knowledge of the whole woman, mind as well as body, before there could be understanding of dysmenorrhoea and the climacteric. They have in common numerous subjective symptoms and a large psychic element and no doubt the complex relationship between nervous system, endocrine system and reproductive organs is involved." EDWARDS (1950) summarises his paper by saying that dysmenorrhoea is an "expression of the total personality of the patient." No social class or build is immune from its curse.

Gynaecologists subdivide its pathology into primary (essential, intrinsic or spasmodic) or secondary (acquired or extrinsic). In the latter group, disease or malformation of the pelvic organs is the cause.

Patients with pain sufficiently severe to cause absence from work or inability to carry on with household duties were classified in the "severe" group. SANES (1918) found that irregularity of menstrual flow combined with dysmenorrhoea favoured an earlier menopause, but Table 8 shows that in this series there was no relationship between dysmenorrhoea and the age of menopause.

| Dysmonorrhoea | No. of Cases | % of Cases | Averagə Agə Menopause |
|---------------|-----------------|---------------|--------------------------|
| Absent | 356 | 79.1 | 48.6 |
| Slight | 62 | 13.8 | 49.6 |
| Severo | 32 | 7.1 | 48.5 |
| Total | 450 | 100.0 | |

TABLE 8 : RELATION OF DYSMENORRHOEA TO MENOPAUSE

The incidence of dysmenorrhoes in both the hospital and in the practice groups can beeseen in Table 8A in the Appendix. Perusal of this table shows a higher incidence of "severe" dysmenorrhoes in the practice group but this was found not to be statistically significant. It may be pertinent at this point to say that no statistical difference in the hospital and practice groups was found with regard to incidence of factors that might affect the age of menopause. Accordingly, Dr. Alwyn Smith found no reason why the two groups should not be combined.

Social Status as it may affect the Age of Menopause

NOVAK (1931) and NAPIER (1897) in surveys of the literature found that poor social conditions were said to favour an early menopause, but Napier maintained that the poor social conditions of the operatives in industrial cities, with their predisposition to general ill health and possible pelvic pathology could not draw a true parallel with the rural peasant.

In this series, women were classified in their social status, according to "Classification of Occupation", published by H.M.S.O. for the General Register Office. Class I is professional and managerial occupations; Class III is skilled artisan occupations; Class V is unskilled and labouring occupations; Classes II and IV are intermediate between I and III, and III and V respectively. Where the woman was a housewife, she was placed in the category referable to her husband. Unfortunately in 19 wemen insufficient information had been taken for appropriate classification. Table 9A in the Appendix contrasts the social status in the hospital and practice groups.

Table 9 shows that no relationship was found between the age of menopause and social status.

TABLE 9 : COMPARING SOCIAL STATUS AND AGE OF MENOPAUSE

| Social Status | No. of Cases | % of Cases | Average Age of Menopause |
|------------------|-----------------|---------------|-----------------------------|
| τ | 28 | 6.2 | 48.8 |
| 11 | 76 | 16.9 | 48.9 |
| TII. | 224 | 49.8 | 48.8 |
| IV | 62 | 13.8 | 48.5 |
| v | 41 | 9.1 | 48.1 |
| Not Known | 19 | 4.2 | 48.6 |
| Total | 450 | 100+0 | 48.7 |

Parity as it may affect the Age of Menopause

KAUPPINEN (1949) in a series of 608 women reiterates the view of the earlier paper of the M.W.F. (1933) in a series of 1220 women that parity bears no relationship to the menopausal age.

SAMES in an earlier study in 1918, based on 621 women, disagrees with this view. He found that "as a general rule" the greater the number of children, the later was the onset of menopause. We found that the relationship was constant whether full-time pregnancies only or full-time pregnancies and abortions were compared with the menopause. After the sixth prognancy, the relationship was not so definite.

In this series only full-time pregnancies are compared with the menopausal age. Table 10A in the Appendix compares the hospital and practice groups and Table 10 shows that in this series "no convincing relationship" (Dr. Alwyn Smith) was found between parity and menopausal age.

Ì

ł

| Number of Pregnancies | No e of Cases | % of Cases | Average Age of Menopause |
|--------------------------|------------------|---------------|-----------------------------|
| None | 129 | 28.7 | 48.5 |
| 1 - 2 | 157 | 34•9 | 48.5 |
| 3 - 4 | . 97 | 21.6 | 49•2 |
| 5 - 7 | 47 | 10•4 | 48•9 |
| 84 | 20 | 4•4 | 49•7 |
| All women | 450 | 100.0 | 48.7 |

TABLE 10 : COMPARING PARITY AND THE AGE OF MENOPAUSE

Certainly one would expect that in order to have many children one would need a long reproductive period and that therefore the more, the longer, but a possible interpretation of the conflicting opinions in literature is that in present society, "heavy" childbearing is generally "over" at an earlier age than in Sanes's series.

Ago of Marriago as it may affort the Ago of Monopolise

BACKMAN (1947), KAUPPINEN (1949) and SANES (1918) hold differing views on this comparison. Backman and Kauppinon are of the opinion that early marriage and an actual sexual life feveur a late monopause; Sanes found that it was the later marriage that was followed by the later cocurrence of monopause.

In this corios, the age of marriage was found not to influence the age of menopeuce. As will be seen from Tables 11 and 12 overleaf, this was found to be valid for all married women and also for married parous women.

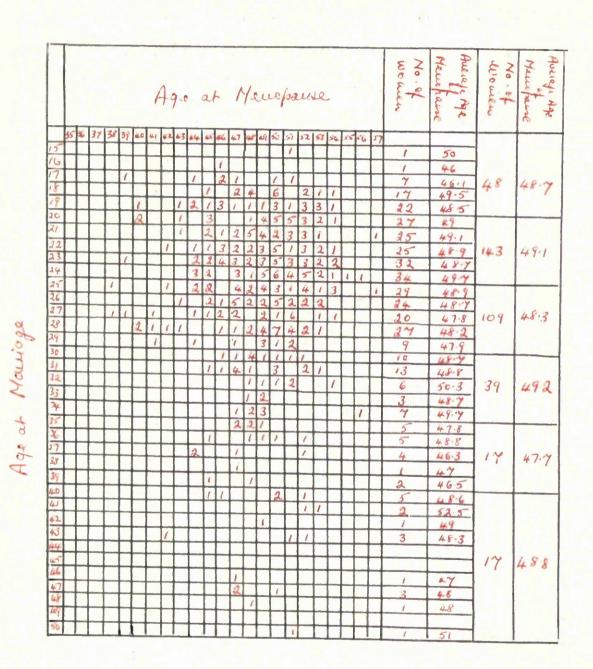

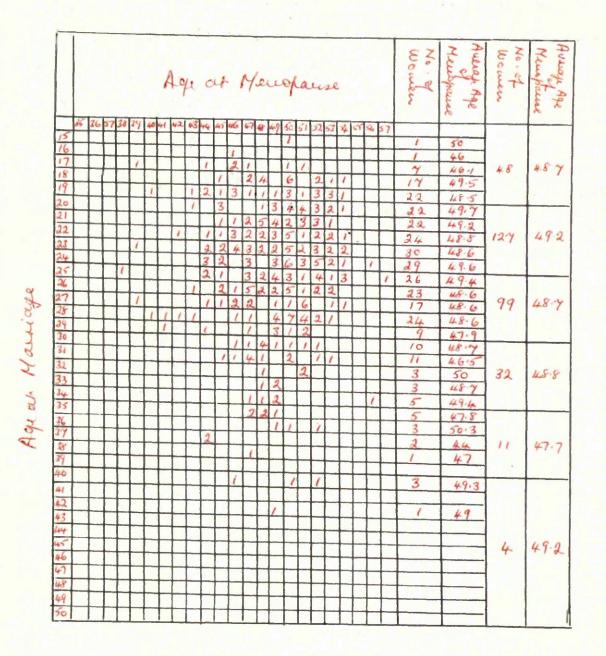

TABLE 11 : AGE OF MARRIAGE AS IT MAY AFFECT AGE OF MENOPAUSE IN ALL MARRIED WOMEN

TABLE 12 : AGE OF MARRIAGE AS IT MAY AFFECT AGE OF MENOPAUSE IN MARRIED PAROUS WOMEN

And at First Promisson as it may affect the Age of Monopause

As Table 13 shows, no relationship was found between the age at first programcy and the age at monopause. Table 13A in the Appendix compares the hespital and practice groups.

No other statistics referable to this comportion could be found in other surveys of the monopause.

TABLE 13 : COMPARING THE AGE AT PIRST PREGNANCY AND THE AGE AT MENOPAUSE

| lgo at Pirot Prognancy | No. of Cases | % of Casos | Averego Ago at Monopeuco |

| <u> 51 - 30</u> | 213 | 47.3 | 49.0 |
| 31 - 40 | 55 | 12.2 | 48.6 |
| 41+ | 6 | 1.3 | 49.0 |
| All women | 450 | 100.0 | 48.7 |

t

Age at last Pregnancy as it may affect the Age of Menopause

SANES (1918) found that with later prognancies there was a corresponding increase in the age of the menopause. KAUPPINEN (1949) disagreed with this view and in a later survey found that there was no such relationship. As Table 14 in this series shows, there was a tendency, though statistical analysis did not justify a definite relationship, for the menopausal age to be later in women who had late pregnancies.

TABLE 14 : COMPARING THE AGE AT LAST PREGNANCY WITH THE AGE AT MENOPAUSE

| Age at Last Prognancy | No. of Cases | % of Cases | Average Age at Menopause |
|--------------------------|-----------------|---------------|-----------------------------|
| 29 | <i>1</i> 7 | 17.1 | 48.3 |
| 30 - 39 | 195 | 43 •3 | 48.8 |
| 40+ | 49 | 10.9 | 49.5 |
| Non-parous | 129 | 28.7 | 48.5 |
| All wom ən | 450 | 100.0 | 48.7 |

A table was then prepared to compare the findings of SANES (1918), KAUPPINEN (1949) and the present series, which found the average age of menopause to be 48.7, 49.06 and 48.7 respectively.

| Age at Last Prognancy | SA No. of Cases | NES % Group | | PINEN % Group | PRESENT No. of Cases | SERIES % Group |
|--------------------------|-----------------------|----------------|-----|------------------|----------------------------|-------------------|
| 29 | 94 | 19.2 | 162 | 29.5 | 77 | 23•9 |
| 30 - 39 | 265 | 54.3 | 245 | 44.6 | 195 | 60.8 |
| 40+ | 128 | 26.5 | 142 | 25.9 | 49 | 15.3 |
| Total. | 487 | 100.0 | 549 | 100.0 | 391 | 100.0 |

TABLE 15 : AGE AT LAST PREGNANCY AND AGE OF MENOPAUSE

Analysis of this Table 15 shows that the commonest age for termination of fertility in all series was between 30 and 40 years and that there is a marked decrease in the 40+ age group with late pregnancies in the present series. This supports the view that childbearing is "over" at an earlier age in present life, as was mentioned previously on page 54.

Marital Status as it may affect the Menopause

SAMES (1918) found that spinsters reached the menopause at a slightly earlier age than the married women (45.3 and 45.87 years respectively). The data in Table 16 in this series show that there is no difference.

| Marital Status | No. of Cases | % of Cases | Avorago Ago at Monopauso | |
|-------------------|-----------------|---------------|-----------------------------|-------|
| Single | 77 | 17.1 | 48.67 | 48.67 |
| Marri.od | 289 | 64+3 | 48.6 | |
| Widowad | 65 | 14.6 | 49.5 | 48.7 |
| Divorced | 2 | 0.2 | 48.0 | |
| Separated | 17 | 3.8 | 48.5 | |
| All women | 450 | 100.0 | | 48.7 |

TABLE 16 : COMPARING MARITAL STATUS WITH THE AGE AT MENOPAUSE

SANES (1918) stated that his finding of an carlier menopause in spinsters was "to be expected." Indeed, a lay attitude might well be that a storile woman whose glands are "ticking over" and not used to their full potential could expect an earlier menopause, but in this series (see Tables 11 and 12) no variation in menopausal age was found between the spinster, the maried sterile woman and the married parous woman.

Blood Pressure and the Age of the Menopause

It was thought of interest to compare blood pressure in the 450 women with the age of menopause. Accordingly Table 17 was prepared. No other similar study was found in the literature, with which to make a comparison.

| Systolic B.P. mm/Hg. | No. of Women | A vorago Ago at Monopauso |
|-------------------------|--------------|-------------------------------------|
| 100 | 19 | 4.7 . 6 |
| 100 - 129 | 164 | 48.2 |
| 130 - 159 | 183 | 48.7 |
| 160 - 189 | 60 | 49.8 |
| 190+ | 23 | 50.3 |
| Not known | 1 | 56.0 |
| All women | 450 | 48.7 |

TABLE 17 : BLOOD PRESSURE AND THE AGE OF MENOPAUSE

This table shows that, as the systolic blood pressure increases, there is a trend towards a later age at menopause. Statistically however the relationship was found not to be significant.

SUMMARY

In 450 women, the average age of menopause was found to be 48.73 years. This age was not influenced by age of puberty, occurrence of pre-monstrual tension or dysmonorrheea, social status, parity, age at marriage, age at first prognamey or marital status. Statistical analysis did not confirm a tendency for menopausal age to be later in women who had late prognancies. Similarly, a trend towards a later menopause in the hypertensive patient was not confirmed by statistical survey.

SYMPTOMS OF THE MENOPAUSE

The occurrence of the elimacteric or hypo-ovarianism is a gradual process, and symptoms attributable to this age may present themselves before the actual menopause or cessation of menses. Similarly, manifestations of the elimacteric may be deferred for months or years after menses have ceased because of continued ovarian function.

The termination of periods may be preceded by various types of menstrual disorder, occurring separately or together - such as irregularity of the periods, scantiness of flow with increased duration (hypomenorrhoea), or excessive bleeding (menorrhagia).

In this series of 450 women, 95 (21%) stated that the periods had been perfectly regular, though possibly less in duration, prior to the menopause. Of the remaining 355 women, various patterns of terminations of periods were claimed. In some, the menstrual flow became less frequent, with periods of amenorrhoea lasting 3-8 months. In others there was a pattern of frequent periods, such as one every two weeks, and a few suffered excessive bleeding, necessitating medical advice.

It might be appropriate at this time to mention that the actual date of menopause was quite vivid to some women, as it had occurred at the time of an emotional crisis, such as the death of a close relative. In one instance it was well remembered by the woman who said: "I havnae seen it since my husband made me snuggle whisky over the Irish border and we was caught!!"

It is generally conceded that the majority of women pass through the climacteric without symptoms severe enough to interfere with their general welfare. However, it was found in this series that 216 women (48%) had consulted their doctors for relief of symptoms itemised in the questionnaire.

Seventy-seven women claimed that they had passed the climacteric with no discomfort whatever. Of the remaining 373, Table 18 illustrates the incidence of symptoms.

| Symptoms | vency in: 450 women | |
|-----------------------------------|------------------------|------|

TABLE 19 8 FREQUENCY OF SYMPTOMS IN HOSPITAL AND PRACTICE GROUPS

FIUSHES

The lucid descriptions given by vemen who experience hot fluches leave little to add. They may vary in intensity from a mild constain of heat in the face and nock, occurring once or twice per day, to frequent opisodes accompanied by profuse sweating and followed by a semention of chilliness. When covers, insomnia may be a troublesome sequel.

The essential cause of flushing, which is regarded by some as the only "true" symptom of the elimactoric, romains That docreased cestrogen secretion, which unicnotta. initiatos the actual monopauso, is the absolute cause of flushing is rofuted. PRATT (1950) stated that in many cases there was no corrolation between the amount of costrogen present and the existence, absence or severity of symptoms. As has already been mentioned, the investigations of FLUIMANN and MURPHY (1939), LAWRENCE and MOULYN (1941), HELLER, FARMEY and MYERS (1944) and othors showed that an excess of the anterior pituitary hormone was the possible responsible factor, and SHARPEY-SCHAFFR (1940) believed that it was the action of the male hormone which cauced a lessening of ocstrogen secretion with a consequent rise in the circulating anterior pltuitary hormone. Yet, HURXTHALL (1951) and

68,

others have found increased genadetrophins in women with no menopausal symptoms. Similarly they state that many wemen with a low level of genadetrophine have pronounced symptoms.

Certainly the glandular imbalance would not seem to be the whole answer. JEFFOOATE (1960) finds that flushing is more troublesome "when the patient is anxious, tense, or otherwise emotionally disturbed." REYNOLDS (1941), in a survey of 18 patients whose primary complaint was severe flushing, found that 11 women who did not respond to cestrogen therapy were relieved of flushing when a demostic or pecial upset was received.

That flushing is under the control of the heat regulating mochanism of the body (based in the autonomic nervous system and the hypothalamus) is emphasized by the "trigger" of a hot meal or atmosphere that the patient often montions.

In this series, fluchings were said to be mild if the woman experienced less than 3 per day, moderate if there were more than 3 but less than 15 per day, and severe if they exceeded 15 in the 24 hours (as with MolAREN'S survey of 1941). Table 20 illustrates the incidence of flushing.

| Sovority of Fluches | Slaglo Womon | Marriod, Widowod, Divorcod & Soparatod Womon | All Women | |
|------------------------|--------------|----------------------------------------------------------|-------------|--|
| Nono | 17 (22%) | 103 (27.6%) | 120 (26.7%) | |
| M1.1.A | 27 (35%) | 130 (34.8%) | 157 (34.9%) | |
| Modorato | 25 (32.6%) | 119 (31.9%) | 144 (32%) | |
| Sovere | 8 (10.4%) | 21 (5.7%) | 29 (6.4%) | |
| Totel | 77 (100%) | 373 (100%) | 450 (100%) | |

TABLE 20 : INCIDENCE OF FLUSIIING

73.3% of women complained of fluching in varying degrees. This figure can be compared with 62.3% in the M.W.F. Survey of 1933 and 70% in a survey of 78 patients by McLANEN (1941). As with this survey, the incidence of fluching in both the MEDICAL WOMEN'S FEDERATION and McLARUN investigations was based on groups of uncollected cases, as opposed to the figures quoted by JONES (1949) and WERNER (1953) of 81.4% and 91.6% in women who "procented themselves for treatment." This higher incidence is comparable with the figure of 88.4% as shown in Table 18, found in the 373 "complainers" in this study. A further attempt was made to assess the intensity of the flushes; they were sub-divided into their greater intensity being nocturnal or diurnal. It will be seen from Table 24 that as the intensity of the fluching increased, so was the patient more liable to be troubled with nocturnal fluching.

| Intensity of Fluching | No. of Women | Tino of Great Diurnal | ost Intensity Nooturnal |
|--------------------------|-----------------|--------------------------|----------------------------|
| 111.1.8 | 157 | 133 (84.7%) | 24 (15.3%) |
| Moderate | 144 | 94 (65.3%) | 50 (34.7%) |
| Severe | 29 | 16 (55.2%) | 13 (44.8%) |
| Total | 330 | 243 (73.8%) | 87 (26.2%) |

TABLE 21 & INCIDENCE OF NOCTURNAL OR DIURNAL FLUSHING

Similarly Table 22 shows that as the intensity of the fluch increases so does the liability to insemmia increase. The accompanisant of sweating with fluching increases too, with the severity of fluching, as is demonstrated in Table 23.

TABLE 22 : FLUENING AND INSOMNIA

| Intonsity of Fluching | No. o? Woman | No. of Women complaining of Incommia |
|--------------------------|-----------------|-----------------------------------------|

| Modorato | 100 | 79 (54.9%) |
| Sovere | 29 | 21 (72,4%) |
| Totel | 3,30 | 129 (39.1%) |

TABLE 23 : FLUSHING AND SWEATING

| Intonsity of Fluching | No. Of Women | No, of Womon complaining of Swoating |
|--------------------------|-----------------|-----------------------------------------|
| M1.1.d | 157 | 77 (49.0%) |
| Modorato | 144 | 123 (84.0%) |
| Sovoro | 29 | 27 (93.1%) |
| Total | 330 | 227 (68.8%) |

It had been noted in practice that a "periodicity" of flushing often seemed to occur. Consequently, each patient was asked if she had noticed whether the flushings were more in evidence at the time of "a missed period." Table 24 shows that of the 330 weren who completed of flushing in varying degree only 116 (35.1%) exhibited this "periodicity" and it was more apparent in weren with moderate or severe flushes.

| Intensity of Flushing | No. of Women | No. of Women who noticed "periodicity" of fluchings |
|--------------------------|-----------------|--------------------------------------------------------|
| ISA 18. | 157 | 38 (24.2%) |
| Modorate | 7 <i>4</i> .a. | 61 (42.2%) |
| forero | 29 | 17 (58.6%) |
| Potal | 330 | 116 (35.1%) |

TABLE 24 & PERIODICITY OF FINSHING

As shown by other authors, symptoms of the elimectoric may be present before the actual constion of monsos. Table 25 shows that of the 330 women with flushes, 122 (36.9%) experienced flushing prior to the menopause, and the more severe the flushing, the more likely were they to have been present before the onset of ememorrhoes. HENDRY (1940) found that 50% of his cases experienced pre-menopausal flushing. This figure is comparable only to the vomen in the "severe" group.

| Intonelty of Fluching | No. of Women | No. of Womon who had Pro-monopausal Flushings |
|--------------------------|-----------------|--------------------------------------------------|
| M11d | 157 | 46 (29.3%) |
| Modorato | 144 | 61 (42.4) |
| Sovoro | 89 | 15 (51.7%) |
| Total | 330 | 122 (36.9%) |

TABLE 25 : INCIDENCE OF PRE-MENOPAUSAL FLUSHING

Because of the alloged connection between a "tense" woman and the occurrence of flushing, a table was prepared relating the incidence of flushing and "irritability and depression". It clearly illustrates that as the severity of flushings increases, so does the incidence of "irritability and depression." The alternative interpretation is that the voman complaining of irritability and/or depression at the time of the elimaeteric is more likely to have concentiant fluches.

| Intonetty of Fluching | | |
|--------------------------|-----|---------------------|
| Nono | 120 | 28 (23.3%) |
| M1.7.d | 157 | 55 (35.1%) |
| Nodorato | 144 | 78 (54.2%) |
| Sovorø | 83 | 25 (86. <i>2</i> %) |
| Total | 450 | 186 (41.3%) |

TABLE 26 : FLUSHING AND IRRITABILITY AND/OR DEPRESSION

As shown carlier, in Table 20, no difference in the incidence of flushing was found in single or married women. A table was propared to find out whether parity bore any relationship to severity of flushes. Table 27 shows that there is no such relationship.

| No. of hildron | Nono | Soverity of Mild | r panonos Modorato | Severe |
|-------------------|------------|---------------------|-----------------------|-----------|
| None | 35 (27.1%) | 48 (37.2%) | 35 (27.1%) | 11 (8.6%) |
| 1 - 2 | 38 (24.2%) | 50 (31.8%) | 60 (38.3%) | 9 (5.7%) |
| 3 as 4 | 31 (31.9%) | 30 (30.9%) | 32 (32,9%) | 4 (4.1%) |
| 5-9+ | 16 (23.8%) | 29 (43.3%) | 17 (23.4%) | 5 (7.5%) |
| Total | 120 | 157 | 144 | 29 |

TABLE 27 : FLUSHING AND PARTEY

In the lay mind, blood presence is occasionally assumed to be linked with fluches. Table 28 shows that there is no relationship between systelic pressure and intensity of fluches.

| TABLE 28 : BLOOD | PRESSURE | AND INTENSIT | y of Flushes |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|

Modical Advice and Freetmont for Women with Fluches

Of the 330 women who complained of flushes in varying degree, 130 (39.4%) sought medical advice and, as Table 29 illustrates, the practice group of women were more liable to sook aid. As would be expected, treatment was more in demand as the intensity of flushes increased.

TABLE 29 : INTENSITY OF FLUSHES AND MEDICAL ATD COMPARING HOSPITAL AND PRACTICE GROUPS

| Intonoity of Fluching | No. ox Hospital | Wordn Goneral Prectico | No. sc Noopital | Practico |
|--------------------------|--------------------|------------------------------|--------------------|-----------|
| Nono | 57 | 63 | erija Grupija | ¢393 |
| M1.1d | 85 | 72 | 8(9.4%) | 14(19.2%) |
| Modorato | 68 | 76 | 37(54.4%) | 47(61.8%) |
| Sovoro | 15 | 14 | 12(80.0%) | 12(85.7%) |
| Total | 225 | 225 | 57(25.3%) | 73(32.4%) |

Further, in the 48 women in when fluching was an isolated complaint, treatment was cought in comparable incidence, as is shown in Table 30.

.

| Intonsity of Flushing | All Womon | Isolated No. of Women | . Fluching No. cooking Aid |
|--------------------------|-----------|--------------------------|-------------------------------|
| 1/1.1.8. | 157 | 33 | 5 (15.1%) |
| Moderato | 144 | 14 | 6 (42,8%) |
| Sovoro | 29 | 1 | 1 (100%) |

TABLE 30 : MEDICAL ADVICE IN <u>48 WOMEN WITH FLUSHING</u> AS AN ISOLATED COMPLAINT

In the hespital group, accuracy as to the exact form of treatment was impossible. In 40 wemen, "pink pills" or "gland pills" were accumed to have been atilboestrol, and in 16 of these wemen there was said to have been an additional godative. Solutives alone were given in three wemen.

In the practice group, 57 women were given attlbeostrol, the most common form of therapy being stillboostrol tabs. B.P. 0.5 mgm. thrice daily for a period of four to five days, gradually reducing to one daily, and stopping therapy after ten to twelve days. In 24 women, additional sedative was given in the form of phonobarbitone tab. gr. $\frac{1}{2}$ toi.d. In women in when nocturnal flushing was particularly troublessmo, combined therapy was given in the form of "Euvalered H" (an Allen & Hanbury proparation containing valerian root, phonobarbitono and stilboostrol) in a dose of one drachm in the merning and two drachms at might. In three women a more recent long-term controgen was given in the form of Tace (a Merrell-National proparation of chlorotrianisons 12 mgm. caps.), which has a fat storage action providing theoretically a gradual release of controgen over a period of three months, after one month's therapy of one capcule twice daily. Two of the women stopped therapy because of namesa, said to be associated with the "eily taste" of the capcule. In four women, phenobarbitone therapy only was given.

Assuming the correct interpretation of the treatment given to the hespital group, Table 31 illustrates treatment in the 130 wemen who sought aid.

TABLE 34 : TREATMENT OF 130 WOMEN WHO SOUGHT MEDICAL AID ON ACCOUNT OF FLUSIES

| Treateont | Hospital Group | Practico Group |
|-----------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Verbal or unknown | 14 | 18 |
| Sedetive only | 3 | анан каландан каландан каландан жанан каландан каландан каландан каландан каландан каландан каландан каландан Дар мактик и каландан кал |
| Stilbostrol only | 24 | 36 |
| Stilbecstrol+sedative | 16 | 21 |
| All womon | 57 | 73 |

A most portinent criticism could be levelled at this high incidence of hormonal therapy, but the author reminds the reader that all the women in the practice received therapy at least one year beyond the actual cossistion of menses, where moderate and graduated decage of stillcostrol gave relief without offending the critics of ill-timed or prolonged stillcostrol therapy.

SUMMARY

Fluchos propent in 330 (73.3%) wenen were found to be unrolated to marital status, parity or blood pressure.

In 48 women, fluching was an isolated compleint.

As the incidence or intensity of flushes increased, so the women were found to be more liable to have concemitant sweatings and/or incommia. Further, the nervous women was found more liable to experience flushing than her calmer sister.

130 women sought medical advice and 2 women were absent from work.

IRRITABILITY AND DEPRESSION

"What about your monopausal cases, doctor?" asks the representative of a drug firm, when he is introducing a new tranguillisor or "anti-depressant" drug. This provalent attitude, combined with a vast literature on the subject of nervous disorders and the menopause, would make one believe that it is uncommon for any woman to pass through the elimactoric without some montal upget.

YOUNG (1939) points out that since the time of Aractous there has been a trend to interpret nervousness in women as a dyefunctioning of the generative organs of the body. 170 thousand years ago it was acceptable to look upon an anxioty state, with its "suffecting symptoms," as being due to an upward wandoring of the uterus exerting pressure upon the STRACHAN and SKOTTOWE (1933) invostigated the diaphram. rolationship botween montal and gynacoological disease in 250 concountivo adult fomalo casos admitted to Cardiff City Montal Hospital. Sluty-one cases (24.4%) of this group were post-monopausal, whilst in their control series of 1000 gynaocological cases in normal montal health, only 10% had It is alaxaing to note that they passed the menopause. quote Moorhead and Flizglbbon citing a case in whom grave mental symptoms at the menopause were relieved by the

removal of the uterus, in which there was "chronic bacterial infection." Fitzgibbon is reported as believing that many memopausal phonomena can be cured by the removal of the uterus, even when no infection is present.

YELLOWINES (1940) and others point out that in the majority of cases of psychological disturbance, slight or severe, at the time of the climactoric, disorders have been present on previous occasions and the monopause apparently precipitates another attack. In a recent paper, DALTON (1959) emphasized the importance of menstruation and the premenstrum in relation to the onset of acute psychiatric opisodes, and reminds the reader that premenstrual tonsion can be successfully treated.

The patient with a true involutional melancholia however has nover had provious mental upset and bodily health is generally affected.

In this series a woman was reckoned to be in the irritability and/or depression group if she had been aware of a definite tension or depression persisting for a noticeable time.

It is depressing to find that 41.3% women fitted into this category. Such a high figure is echoed in other

surveys - 30.9% (ITEDICAL WOMEN'S FEDERATION, 1933) and 43.0% (GULDBERG and LUND, 1954).

Of the 186 women affected with irritability and/or depression, 96 were in the hospital group and 90 in the practice group. In no instance was this an isolated complaint. An attempt was made to relate pro-menstrual tension, marital status, parity and social status to this irritability and/or depression group.

| PABLE 32 | 8 RELATION | TRANS FIO | INSPRUAL | TENSTON |
|----------|------------|-----------|----------|---------|
| AND | IRRITABILI | TY AND/OR | DEPRISSI | 01 |

| Pro- nonstrual. Ponsion | Womor Rosp. | Prac. | Womon oon of Irrite and/or De Hosp. | bility prossion: Prac. | All Womor |
|-------------------------------|----------------|-------|----------------------------------------------|------------------------------|-------------|
| Авсэнг | 174 | 165 | 68 | 63 | 131 (38.6%) |
| 53.i.64* | 40 | 48 | 20 | 22 | 42 (47.7%) |
| Severo | 11 | 12 | 8 | 5 | 13 (78.3%) |
| Total | 225 | 225 | 96 | 90' | 186 |

Table 32 clearly illustrates that a woman suffering from pro-menstrual tension is more liable to suffer from "menopausal nervousness" and the more severe the pro-menstrual tension, the more likely is the secuel.

AND IRRITABILITY AND/OR DEPRESSION

| Marital Status | Women ins Hosp. Prac. | | Women complaining of Trritability and/or Depressions Hoop. Prac. | | All Wongn |
|-------------------|--------------------------|-----|---------------------------------------------------------------------------|------|-------------|
| Singlo | 26 | 51 | 8 | . 16 | 24 (31.2%) |
| Marriod | 199 | 174 | 88 | 74 | 162 (43.5%) |
| Total | 552 | 225 | 96 | , 90 | 186 |

Table 33 shows that the single women is less likely to complain of irritability and/or depression at the memopause. Statistically, however, the relationship is not significant: (Difference = 12.3%; S.E. = 6.6%; therefore the difference is not significant). It may be that the busy single vomanhas a different attitude to the memopause, or maybe her life does not allow for the "tantruns of the elimestoric". Such a statement would no doubt bring applauce from several quarters.

TABLE 34 8 RELATION OF PARITY AND TRRITABILITY AND/OR DEPRESSION

| Prognancios | Новр. | a in: Prac. | of Irrite | nplaining ability oproseion Prao. | All Womon |
|-------------|----------|----------------|-----------|--------------------------------------------|-----------|
| Nono | 50 | 79 | 18 | 26 | 44(34.1%) |
| 1 - 2 | 75 | 82 | 34 | 37 | 71(45.2%) |
| 3 - 4 | 55 | 42 | 24 | 17 | 41(42.3%) |
| 5 - 7 | 34 | 13 | 16 | 6 | 22(46.9%) |
| 8-2- | 11 | 9 | Ą. | 4 | 8(40.0%) |
| Total | 225 2 | 225 | 96 | 90 | 186 |

As Tablo 34 shows, no relationship was found to exist between parity and incidence of irritability and/or depression.

TABLE 35 & RELATION OF SOCIAL STATUS AND IRRITABILITY AND/OR DEPRESSION

| Sociel Status | | n ins Prac. | of Irrite and/or De Hosp. | oprosaion Prac. | All Womon |

| Total | 552 | 225 | 96 | 90 | 186 |

That no relationship is found between social status (as defined on p. 51) and the incidence of irritability and/or depression (as shown in Table 35) is at variance with the findings of XELLOWLEES (1940), who reported a greater incidence ("about 1 in 5") of women in the 42-52 age group referred for advice in his private practice, as opposed to "less than 1 in 10" in the same age group referred to a psychiatric clinic.

Modical Advice and Troctment of Wemen complaining of Irritability and/or Deproceion

Dospite the high incidence of "irritability and/or depression" found in this series, only 39 women (20.9%) sought modical advice, 24 being from the practice group and 15 from the hospital group. Seven women were incapacitated as a result.

Solativos given were various, but phenobarbitone was the main therapy in 11 cases; other drugs given were "Bellargal" (Sandoz proparation of alkaloids of belladonna, ergetamine tartrate and phenobarbitone), "Drinemyl" (Smith, Klein & French proparation of decompletamine and anylobarbitone) and codative "bettles."

In two instances, psychiatric treatment was required, and one woman was hospitalised for such thorapy.

SUMMARY

Irritability and/or depression was present in 186 (41.3%) of the women and, as a symptom of the climactorie, was never an isolated complaint. It is most likely to occur in a women who had proviously suffered from premenstrual tension and there was some ovidence to suggest that the single women was less prone to complain of "nervousness." Parity and social status were found not to influence its incidence.

. .

87.

Modical advice was sought by 39 women and 7 women were absent from work.

VERTIGO

Vertige, as found during the menopause, may occur at intervals of days or even weeks, while in some cases it may happen coveral times in a day. In most instances the patient complained of a sense of rotation around them of visible objects, and in the majority of instances it was reputed to be annoying ("a mild disziness") rather than incepacitating.

Of the 143 women (31.8%) found to have this complaint, 75 weaen were in the practice group and 68 wore in the hespital group. The MEDICAL WOMEN'S FEDERATION survey in 1933 found an incidence of 39.7% and JONES (1949) and WERNER (1953) found widely differing incidences of 5.4% and 67.4%. In these two latter groups, the patients presented themselves for treatment and were therefore selected.

In only one instance was vertige an isolated complaint.

In his article on vertige of the menopause, SAMES (1919) found that in a series of 102 cases of menopausal women, 46% women with vertige had a blood pressure exceeding 150 mm/Ng. and "only 20% or 30%" above 160 mm/Ng. This high incidence of hyperpicals was not found in this series. Table 36 was prepared to illustrate the distribution of systelle blood pressure in these who did and did not have vertige.

TABLE 36 : ANTERIAL DLOOD PRESSURE AND MENOPAUSAL VENTIGO IN A49 WOMEN

| ייז איז איז איז איז איז איז איז איז איז | Systolic Blood Prossure in ma/Hg. Baccoding 150 Baccoding 160 | | |
|-----------------------------------------|--------------------------------------------------------------------|---------|--|
| All voider (449) | 25.8% | <u></u> | |
| 143 women with vertigo | 31.5% | 21.8% | |
| 306 women without vertige | 23•5% | 16.9% | |

This analysis shows that a woman with hypertonsion is more liable to have a complaint of vortige than a woman with less cloveted blood pressure.

<u>Medical Advice and Treatment</u> for Wemen complaining of Vertige

Medical advice was cought by 18 (12.6%) women, 9 in each of the hospital and practice groups. Vertige was never so severe as to be a cause of loss of work.

In two women - Gase Nos. 81 and 124 - iron injectionswere given to combat ansamia resultant from a gustrie ulcor and hasmorrhoids respectively. It is possible that in these cases the vertige was a sequel of ansamia. In Case No. 366 of the practice group, iron therapy was given, but no details are available as to the cause of ansamia in this patient. Six women (33.3%) had a blood pressure exceeding 160 mm/Hg.

SUMMARY

Vortigo was present in 143 (31.8%) women and in these women a higher incidence of hypertension was found than in the eases with no complaint of vortige.

As an isolated symptom, vortige was present in only one case.

Of the 18 women who sought modical advice, breakdown of the thorapy suggested a pathology other than hormonal imbalance as the cause of vertige in 50% of the women.

In no case was vertige severe enough to cause absonce from work or demostic duties.

UNDUR PATIONS

. :

ī

t

This quotion of undue fatigue was found to be the most difficult for the patients to answer; as far as many women were concerned, a feeling of fatigue at the end of a day's bering housework or routine was almost regarded as commonplace and not a true complaint. They might well reply: "Oh, yes" when asked if they felt tired, and then correct themselves by saying: "No, not really!" Its accuracy could easily be questioned. So convinced was the author of this that further analysis was considered irrelevant. This opinion is enhanced by the fact that the five women who were incapacitated by the symptom of "undue fatigue" were in fact treated for a general systemic disease.

125 women admitted to the feeling of undue fatigue coincidental with constition of mensor, 61 women wore in the hespital group and 64 in the practice. In the hespital group, 16 women cought medical advice, and in the practice group the figure was 9. In no case was it an isolated symptom.

HBADACHB

:

The headeches encountered at the monopause are described as a sense of intense pressure in "the top of the head". MONTCOMERY (1945) found that, in patients who suffered from headaches prior to the monopause, they became more frequent and severe with constition of monses. TH LINDH (1954) on the other hand claims that the monopausal headache is quite different in character from head pain found at other ages. It is agreed that they may be influenced by variation of blood pressure, or by emotional tension associated with anxiety, but their true origin is uncertain. MONTCOMERX (1945) states that they may be associated with "disturbances in the pituitary".

The incidence of headache in this report was found to be 27.3%: other series quote 29.5% (GULDBERG and LUND, 1954), 44.6% (M.W.F., 1933) and 5.4% (JONES, 1949).

Of the 123 patients who edultted to headaches, 69 were in the hospital group and 54 in the practice group. In 3 instances only was this an isolated complaint.

Of the 123 women, it was of interest to note that concentiont "irritability and depression" were present in 84 women, and the impression in a surgery of a monopausal

headache is a "tonsion" phonemonon, with the vemen characteristically pressing the tomples of the head as if to seek relief. This gesture is often seen in a younger person complaining of pre-monstrual tension. Accordingly, Table 39 was prepared to show whether any relationship could be found between cases complaining of pre-monstrual tension and these complaining of headaches at the monopause.

:

TABLE 39 : RELATIONSHIP DETWEEN PRE-MENSTRUAL TENSION AND HEADACHES AT THE MENOPAUSE

| Pro-nonstrual Tonsion (in 450 casos) | No. of Women | No. of Women compleining of Hoedecho | Porcontago of oach Group |
|-----------------------------------------------------------------------|-----------------|--------------------------------------------|--------------------------------|
| Nono | 339 | 78 | 83.1 |
| sili ga t | 88 | 33 | 37.5 |
| Severo | 23 | 12 | 52.2 |
| POUS CONTRACT, AND CONTRACTOR AND | 450 | 123 | 27.3 |

It was found that as the tendency to pro-monstrual tension increased so did the likelihood of headache become manifest.

A further table was propared to find the incidence of hypertonsion in the menopausal woman suffering from headache.

95 i

TABLE 40 : ARTERIAL BLOOD PRESSURE AND MENOPAUSAL READACHES IN 449 WOMEN

| nan karan dan karan dan menangkan kenangkan karan dara karan karan dan karan dan berangka menangkan karan para Karan karan karan karan karan kenangkan karan dara karan karan karan dan kenan dara kerangkar berangkan karan k | | rossuro in mn/Hg. |

| A12. WORRER | 25.8% | 18.5% |
| 123 vonon with hoadacho | 31.6% | 25.3% |
| 326 woxen without headache | 23.0% | 15.9% |

As would be expected, Table 40 shows that the hyperplotic woman is more liable to suffer from boadaches at the climactoric.

Meddeal Advice and Treatmont of Menopausel Headaches

As with other monopausal complaints, the symptoms must be estimated principally on whether or not the patient cought modical aid. Of the 69 heapital cases, 16 women cought modical advice and in the practice group of 54 women, 13 cought aid. Of these 29 women, 25 (86.2%) had a concentiant symptom of irritability and/or depression and 14 (48.2%) had a cystolic blood pressure exceeding 160 mm/Hg. In two cases, hypertension was a cause of hospitalization.

Tablos 41 and 42 illustrato the treatment of the 29 women who sought modical advice. TABLE 41 : PATTENTS WITH READACHE WHO SOUCHT EIDDICAL AID GENERAL PRACTICE GROUP

TABLE A2 : PATIENTS VITE READACEE VEO SOUGHT NEDICAL ATO HOSPITAL GROUP

SUMMARY

123 (27.3%) women complained of headache at the time of the elimactoric. In 3 women only was this an isolated complaint.

It was found to be more evident in the women who had experienced pre-monstrual tension and was commonly associated with a complaint of nervousness and/or irritability. In 31.6% of the women there was a systelic blood pressure exceeding 150 mm/Hg. In 29 women modical advice was cought and in this group the incidence of hypertension was 48.2% and of irritability and/or depression 86.2%.

In no instance was headacho a cauco of loss of work.

OBESTTY

The characteristic obecity of the menopause is found particularly over the hips and girdle region. Authors argue its cause, some refuting the suggestion that obecity at the elimeeteric is necessarily a subclinical endoorine deficiency. Another view is veiced by HANPER (1950), who found a concential corvical infection in cases he was treating for post-partum or menopeusal obseity, and when the infection was treated, the less of weight was greater than if the caleries were restricted without any treatment of infection. A simpler explanation had been suggested earlier by LANGDON-DROWN (1935), who attributed its cause to wemen allowing themselves to become "slack physically." He stated: "It is easier for a merried woman to coddle hercelf than for her unmarried sister".

A woman was said to be obese in this review if her weight gain had exceeded 1 stone since cossistion of momens. The majority of women who admitted to weight increase had gained 1 - 2 stones.

The figure of 114 woman (25.3%) found to be in the "obese" group in this survey is less than in other surveys.

ŕ

1

The MEDICAL WOMEN'S FEDERATION (1933) found an incidence of 34.2%, and in Norway GULDBERG and LUND (1954) found that 32.6% woman admitted increase in weight. No indication is given in these reviews as to notual weight gain.

In the 1933 report of the MEDICAL WOMEN'S FEDERATION, the obselty was found to be more marked in married women, where the percentage was 39.4% as opposed to 22.7% in single women; this finding is reiterated in the figures of 27.1% and 16.9% in this series, echoing LANGDON-BROWN's sentiment.

Of the 114 women, 66 were in the hospital group and 48 in the practice group. In only 3 women was obsaity an isolated complaint. 101 women were found to have no co-existent complaint of loucorrhoes, which could be indicative of a concentrant cervical infection. Medical Advice and Treatment of Menopeusal Obesity

Ninotoon women sought modical aid because of obseivy, 14 in the hospital group and 5 in the practice group. All but one wore married and all but three wore parents.

Tablos 43 and 44 illustrato the treatment given.

Of interest is the fact that five women had a concentiant complaint of changes in the skin and/or hair, an incidence of 26.8% in the group of these seeking aid - far in excess of the 8.7% women in the whole series.

The question of hypothyroidism at the monopauce will be discussed later (see p. 130) and if the complaint of changes in the skin and/or hair can be blamed on a hormonal basis, then its high incidence in these complaining of obcalty is not surprising.

TABLE AA : TREATMENT OF 19 WOMEN WHO SOUGHT MEDICAL ATD FOR OBESITY

GEIMERAL PRACTICE GROUP

SUMMARY

114 (25.3%) women had a weight gain exceeding 1 stone subsequent to concation of monces, and its incidence was greater in the married women than in the spinster (27.1% : 16.9%). In only 3 women was it an isolated complaint.

No evidence was found to support a theory that obspity was more evident if associated with a corvical infection, but a possible hormonal link was established.

Mineteen women cought modical advice, and obesity was nover a cause of loss of work.

REEUMATIC PAINS

A survey of the literature shows that many authors doubt the existence of "menopsues.] arthritis" or "menopsues.] arthralgia" as a separate entity. ROGERS (1956) reminds us however that joint pains in women at the menopausal epoch are five times nore common than in men of a comparable cas THOMSON (1936) and GREEN ARMYTAGE (1957) describe group. the affliction as an arthritis affocting particularly the knoos and occasionally other joints. Thomson states that in many sufferers obssity, hypothyroldism or flat feet may be found, and Groon Armytage rominds his readers that at the climactoric the pelvic floor is liable to sag and may give rise to backache and generalized aches and paine. WERNER (1953) found that the joints most affected in his series of ceses were the fingers, hands, wrists, shouldors and spine.

As with the M.W.F. survey of 1933, the term "rheumatic pains" in this review is taken in a very "unscientific sense" and any woman admitting to a mild form of fibrositic or a more advanced pathological arthritic was assumed to be a sufferer from "rheumatic pains." 105 women (23.3%) came within this group, 60 being in the practice and 45 in the hospital group. As an isolated complaint, it was present in only three women.

The M.W.F. (1933) and JONES (1949) found incidences of 23.7% and 17.2% in women suffering from "rhoumatic paine" or "vague and indefinite paine."

An attempt was made to analyse the 105 women in this survey, and the possible association with obsaity, bad posture or hypothyroidism, assuming that the latter was present if the woman admitted to "changes in the skin and/or hair."

TABLE 45 : PATIENTS EXHIBITING OFFICE SYMPTOMS IN ASSOCIATION WITH "RHEUMATIC PAINS" IN 105 WOMEN

This analysis shows that 57 women had no concentant complaint of obseity, backache or changes in the skin and hair.

Medical Advice and Treatment of Menopeusal Wemen with "Rhoumetic Paine"

Of the 60 women in the practice group admitting "rhoumatic pains," 22 sought modical advice and in the hospital group of 45 "complainers," 15 women sought aid. In these 37 women, 19 (51.4%) had no associated backache, obesity or changes in the skin and hair. The treatment given is itemiced in Tables 46 and 47. Six women were incapacitated because of "rhoumatic pains."

SUMMARY

105 (23.3%) women admitted to "rhoumatic pains," and as an isolated complaint this was procent in 3 women. In 37 instances modical aid was sought and, excluding fluches, it was the most common symptom for which medical advice was requested.

In this group, 51.4% women had a concentant complaint that could have been the basis of the "rhoumatic pains."

Six women lost work because of "rheumstic pains."

BACKACHE

To a general practitioner, the complaint of backache in a housewife is a common occurrence. The frequent banding and lifting in normal routine household chores must surely exert a great deal of strain on the lumbar vertebrae and sacro-iliae joints. WERNER (1953) found the lumbosacral area of the spine the most frequently affected, and LANGDON-BROWN (1935) observed that multipara commonly have a recurrence of chronic backache at the time of the menopause. Other authors lay the blame for this symptom in some cases at the door of obesity, prolapse or a sequel of pelvie pathology.

Within the last twenty years, interest has been aroused in the condition of post-menopausal esteeporosis. Albright in 1940 was the first author to succeed in clearly defining the condition. The majority of his patients were women in their fifties, all of when had amemorrhoes. The soticlogy of this pre-semile esteeporosis remains obscure, despite the knowledge that ovarian function is related to calcium metabolism and the administration of costrogens or testesterone gives relief to the patient suffering from this malady. Some authors believe that the administration

of sex hormones has a general anabolic effect on metabolics, thus promoting proliferation of tissues of various kinds. DOMALDSON and NASSIM (1954) remind the reader that a moderate degree of esteoperests of the spine is almost physiological at the time of the menopause.

Only 62 women (13.8%) admitted to backsche, 24 from the hospital group and 38 from the practice group. It was nover an isolated sympton.

Analysis of these women showed that only 20 were multipercus. Furthermore, an attempt was made to find how many of the 62 women might have an accompanying obseity, leucorrhoes or bloeding lasting ten days or longer before final cossition of mences, or rhoumatic pains.

1110

Table 48 (p. 111) shows that 24 women (38.7%) out of the 62 women complaining of backache had no concemitant symptom which could be the direct cause of the backache.

<u>Medical Advice and Treatment of 62 Menopausal Women</u> with Backache

Fifteen women sought medical aid, ten from the practice group and five from the hospital group. All but one was parents. The following table illustrates treatment. Unfortunately, in no instance was an x-ray of spine studied and it is not known whether esteeperesis was present in any case.

Of these 15 women who sought medical advice, 9 (63.6%) had a concemitant complaint which could have been the cause responsible for the backache. Five women were absent from works or demostic duties because of backache.

SUMMARY

I

62 women (13.8%) admitted to a cymptom of backacho. In no case was it an isolated cymptom. A possible basis for the backache was found in 61.3% of these women and in the 15 women who cought medical aid, 9 women had concemitant symptoms that could have been responsible for the backache.

Five women lest work because of backache.

INSOMNIA

MALLESON (1953) has pointed out the emission of this symptom in the M.W.F. survey of 1933. Since 92 (20.4%) women in this series were complainers, it obviously deserves inclusion in discussion. Of these 92 wemen, 40 were in the practice group and 52 in the hospital group. In no instance was incommis an isolated symptom. JONES (1949) found a smaller incidence of 13.2% in his cases.

Incomnia at the menopeuse is frequently blamed on fluches occurring at night, and 74 women had a coexistent complaint of fluches. In 9 women who had no fluches, 6 had a blood pressure exceeding 160 mm/Hg. systelic. A table was propared to illustrate the possible connection between incomnia and fluches and blood pressure.

| Fluchos | No. o? | No. of Women with Nocturnal Pluehing or Sweating | No. of Women with B.P. exceeding 160 mm. Systelle |
|----------|--------|--------------------------------------------------------|---------------------------------------------------------|

| Sovoro | 15 | 15 | 3 |
| Total | 92 | 74 | 68 |

I

TABLE 51 : FLUSHES IN 92 WOMEN COMPLAINING OF INSOMNIA

Table 51 (p. 115) shows that the flushes could have caused the insemnia in 74 cases (78.3%) and further that 29 wemen (31.5%) had a systelle blood procease exceeding 160 mm. A later discussion will show that of the 450 wemen in this series, only 83 or 18.5% of all the women had a hypertension exceeding 160 mm. The larger percentage of 31.5% procent in the incommit group supports the view that hypertension plays a rôle in the complaint of sleeplesences at the time of the elimactoric. (Statistically the difference is 16.4%with a S.E. of 4.5).

Modical Advice and Treatmont of Women with Incomnia

Of the 92 women with insomnia, 24 sought medical advice, 10 being from the practice group and 14 from the hospital group. In 15 (62.5%) of these women, fluches were caid to be the cause of the sleepleseness. In 11 women, systelic blood pressure exceeded 160 mm./Hg., an incidence of 45.8%.

As was stated carlier, insemnia was never an isolated symptom and in the group of 24 "complainers", it was an isolated "complaint" from only one woman. Further perusal of the questionnaires shows that in most instances treatment for insemnia was directed at the cause of the sleeploseness rather than as a hypnotic on its own.

SUMMARX

.

Incomnia as a symptom of the clinacteric was prosent in 92 women (20.4%) and was never isolated. It was found to be frequently associated with moderate and severe flushing and the incidence of hyperpictic was found to be higher in this "incomnia" group than in the whole cories.

Twoaty-four women sought modical advice.

PRURITUS VULVAE

In a comprohensive paper on the dermatores of the menopause, BARBER (1946) found that pruritus, localized or generalized, as a neurodormatitic is a "frequent" symptom of the elimectoric. MeLAREN (1953) emphasized that treatment must essentially be firm reasourance combined possibly with sodation, "as anxiety is the basic cause in the majority of these cases." GREEN-ARMYTAGE (1957) considered incommic a "devastating" sequel of pruritue.

39 women (8.7%) complained of pruritus vulves in this cerice, 11 from the hospital group and 28 from the practice. In no instance was this an isolated complaint. 27 of the 39 women also admitted to "irritability and/or depression" and this fact enhances Melaren's view on this topic and the 11 women who had a coexistent insomnia echo Green-Armytage's opinion.

Further analysis of the 39 women was tackled to discover whether the symptom of pruritus could be a sequel of other factors, such as leucorrhoea, obssity (causing a localised occoma), or a systemic illness (for example, diabetes mellitus), as well as an expression of an anxiety state.

,

Tablos 54 and 55 were propared and careful perusal reveals that in 37 of the 39 women a concemitant symptom could have been responsible for the pruritas.

TABLE 55 : GENERAL PRACETOE GROUP (continued)

Modical Advice and Treatmont of 39 Monopausal Women with Prunitys Vulveo

Of the 39 women admitting to pruritue vulvae, 4 sought medical advice, 2 from each of the hospital and practice groups. In two instances (Cases 52 and 505), treatment was directed at the systemic illness of diabetes mellitus; and in Case 168 "pessaries and diet" were preceribed. In Case 485, a local therapy of 1% ichthyol in calamine linimont was given in combination with sedative therapy for an extremely approhensive patient.

Unfortunately, it is not known what medicament was contained in the pessaries given to Case 168. Some practitioners believe that costrogens either locally or systemically will prove of value, although McLAREN (1953) condemns their use as the condition may be aggrevated by causing a local codema of the vulves with increased vascularity. It is of interest to note that SAVILL (1937) advocated the use of diathormy, stating that the beneficial action was possibly due to ovarian stimulation by the current.

The purely local condition of kraurosis vulves was not present in any case. In a survey of cases attending the TEL AVIV Hospital, with menopausal complaints, MENDERGER (1953) found that 6.6% women complained of pruritus and of these "about 25% were found to have kraurosis vulves." A local condition such as this must be carefully excluded.

SUMMARY

39 women (8.7%) admitted to pruritus vulvae and in no instance was this an isolated symptom. 27 of these women (69.2%) had coexistent irritability and/or depression. 17 women (43.6%) were obese and 20 (51.4%) had leucorrhoea as opposed to the incidence of 41.3%, 23.3% and 8.4% for these respective symptoms in the whole cories. In all only 2 women did not have these concentions, suggesting that the symptom of pruritus should be regarded as a secondary symptom. In 2 of the 4 weren cocking medical aid, diabetes mellitus was present.

LEUCORRHOEA

The presence of loucorrhoes in a paper on the menopause might suggest that it is more common in middle age than at any other time in a voman's life. This is certainly not the author's impression. The adoloscont and young married women seek advice for lewcorrhoes more frequently then one would expect from gyneecological teaching. On occasions. thoro can bo a real foar on the part of the patient and whether the persistence of unwarranted complaint means fear of censor or of vonorcal disease is often difficult to Thore is an apparent difference in the almost dotormino. casual way in which a middle aged woman will prosent with leveorrhoes, and here the prectitioner may be more worried than the pationt.

38 women in the series had noticed vaginal discharge, 17 in the hospital group and 21 in the practice group. In 22 women there was an accompanying pruritus valvae, and this high incidence surprises the author as in the younger age group pruritus is mentioned only occasionally as a partner of loucorrhoea.

Modical Advice and Treatment of 38 Wemen with Loucotrhooa

Only 7 women sought modical advice, which would onhance the author's impression of the casual attitude of many middle aged women to leveerrheea. Pruritus vulvae was present in 5 women. Pessary therapy was given to 5 of the women, although unfortunately it is not know what modicament was in the pessaries. In one case, no treatment was given and in the seventh women a dilatation and curettage revealed the presence of a pyemetra.

SUMMARY

38 women (8.4%)had loucerrhoes. In 22 women there was an associated pruritus vulvae. In 1 of the 7 women socking modical advice, work was lost because of gynaecological investigation which, subsequent to dilatation and eurottage, revealed a pyenetra.

PAINS IN BREASTS

In a paper discussing the possible relationship between the monopause and the age at onset of breast cancer, ANDERSON, REED, HUSEBY and OLIVER (1950) conclude: "It seems ontirely possible that the hormonal changes at the monopause might temperarily affect the incidence of breast cancer," although further studies would be necessary to establish the relationship.

The description given by patients of a "heaviness" or disconfort in the breasts occasionally accompanied by sharp shooting pains reminded the author of the description of disconfort in the breasts experienced by patients premenstrually. As has already been mentioned, MALLESON (1953) blames this on imbalance of the progesterone/ costrogen ratio. The high costrogen levels of premenstrual tension cannot be correlated with the low costrogen levels of the elimactoric: it is of interest to note that all 29 women who admitted to pains in the breasts had accompanying flushes. This latter fact would certainly suggest a hormonal imbalance as being responsible but not analogous to that found premenstrually.

In the 29 women (6.4%) who admitted to experiencing pains in the breasts, 10 women were in the hospital group and 19 were in the practice group. In no instance was there a breast pathology.

In one instance only was the disconfort so severe that modical advice was sought. No treatment was given.

Survey of the literature shows that only the N.W.F. (1933) report investigated pains in breasts as a symptom of the menopause. Here an incidence of 6.3% was reported.

SUMMARY

The fact that all the 29 women (6.4%) who admitted to pains in breasts had flushes would suggest a possible hormonal basis for this symptom. No treatment was given to the one woman who cought medical advice and it would appear that this symptom is not of an incapacitating nature.

OHANGES IN THE SKIN AND HAIR

Nore a general practitioner is treading dangerous ground. Are there changes in the thyroid gland at the time of the menopause sufficient to cause apparent physical changes? One member of the steering committee had been approached by a practitioner in Oxford who falt, after some years of practice, that a sub-thyroid condition, maybe subclinical, was apparent in some menopausal patients when she had known over several years. Thus, the women in this ceries were asked if they had noticed any changes in the ekin or hair.

Perusal of the literature leaves the author wondering. COLLETT (1948) states: "A fall in B.M.R. is to be expected along with an increase in weight." She also attributes the fatigue experienced by some women at the monopause to reduced thyroid secretion. LANCASTER (1953) refers to an alopecia - particularly intractable to treatment - of a hypothyroid variety at the elimactoric. WOHL and PASTOR (1944) on the other hand refer to an elevated B.M.R. as a ecomon occurrence at the monopause with concemitant signs of hyperthyroidism such as irritability and palpitation. The general practitioner can only agree with both.

39 women (8.7%) admitted to a difference in the texture of the skin and/or hair. 20 women were in the hospital group and 19 in the practice group. In no case was it an isolated symptom.

In 2 instances only was the change to the bonefit of the women, who claimed that their complexions had become much "clearer." The majority of the women had noticed a "drying" or "thinning" of the hair and none had noticed an increase of hair growth that FREED (1950) claimed might be caused by an over-proponderance of the androgene.

As far as increase in weight is concerned, 13 women in this group (33.3%) were also sufferers from obseity, a figure slightly higher than the incidence of 25.3% for the whole series.

The literature suggests that, as far as skin pathology is concorned, nourodormatitie is the most commonly encountered at the menopause (BARBER, 1946; ROGERS, 1956). In this series, only one woman admitted to "nottlorach" but she had not cought medical advice.

WERNER (1935) and GOLDBERG (1936) claim that personthomic is found in at losst 25% monophusel women. None was seen in this series, but the author has since seen two cases. One of these women was eventually referred to hospital where she was assumed to be "in the menopause" and after persistent complaint with no benefit from therapy, which included centrogens, the hospital authorities advised a psychiatric opinion. This advice displeased the patient to such an extent that she refused to co-operate further. She then left the district and last year the author was informed that she had been eduitted to hospital with a diagnosis of disconinated sclerosis. Such are the dangers of labelling a patient "in the menopause."

Medical Advice and Treatment of 39 Wemen with Changes in the Stin and/or Hair

Three women sought medical advice. In two instances, thyroid was given and in the other cytamen injections. There was apparent benefit in all three cases but only after several months, when possibly other factors, including Mother Nature, may have come into play. The reasons for the therapies seem to have been entirely empirical, as no evidence of anomia or myxoodems was present.

SUMMARY

Changes in the skin and hair never constituted an isolated symptom. Such changes were present in 39 weren (8.7%). They were never so blatant as to be obviously attributable to a sub-thyroid condition but there was a slightly higher incidence of obesity in this group than in the whole series.

Three women cought modical advice and the treatment given appeared to be of a placebe variety.

EXCLESSIVE BLEEDING

JEFFCOATE (1960) correctly points out that heavy utorine blooding is never a manifestation of the memopause (as such an occurrence cannot be caused by a constituent of ovarian function) and should never be treated symptomatically. Nevertheless, it was considered of value to determine how many women had suffered memorrhagia before the actual constition of memors.

Twonty-sovon women or 6% of the series, 14 in the hospital group and 13 in the practice group, admitted to excessive vaginal bleeding lasting ten days or longer. In no instance was this an isolated symptom. Since each of these 27 women continued on to a normal menopause, it must be assumed that in this group no gross pathology was found meccessitating major operative intervention.

Invastigation of the menstrual pattern of those 27 women showed that 23 (85.2%) of them had an irregular pattern of menses for some months before the actual menopause. This compares closely with the figure of 78.9% women who had no gross menorrhagia but had an irregular pattern of mensec.

HAWKINSON (1938) cites a figure of 14.3% menopausal women with menorrhagia, GULDDURC and LUND (1954) a figure of

12.8% and the M.W.F. (1933) 20.9%. It is unfortunate that none of these authors defines the duration and coverity of the excessive bleeding. This may well account for the variation in the figures.

Modical Advice and Treatmont of 27 Women with Memorrhagia

Twonty women cought modical advice and, as will be seen later in Table 79, excessive blooding as a provailing symptom was the most common cause of work incapacity - that ic, assuming that monorrhagia is reckoned to be a monopausal symptom. Two of the women who sought advice were single, and of the 18 married or widowed women, all but 4 were parous.

A point of interest, although numbers do not warrant a statistical observation, is that of the 20 women who sought medical advice, 6 (30%) had a systellic blood pressure exceeding 160 mm/Hg. This is a higher incidence of hyperpiests than was found in the whole series - namely 18.5%.

In 5 women, dilatation and curatings was the treatment prescribed. In the remaining 15 wemen, the bedrogks of therapy were rest and iron. Twelve women were incapacitated.

SUNMARY

í

The incidence of memorrhagie - that is, menses persisting for longer than ten days - was found to be 6% and it was never an isolated symptom. Of the 27 women with excessive blooding, 20 sought medical advice and 12 were absent from work.

LIETDO AND DYSPAREUNTA

J. P. PRAFT (1950) states that the foar of loss of sexual activity ranks next to the fear of old age. Indeed, he says that these foars are often appreciated as being one and the same. WHED (1953) points out that libide generally ceases earlier in women than in men, often to the woman's discomfiture and to the detriment of both. PRATT (1950) states that this may be only a temporary lull.

Many women interviewed regarded the advent of the memopause as a convenient excuse for abandoning sexual union, admitting on further questioning that "I never liked it anyway." In the women who were genuinely distressed by the loss of libido, reassurance that the lessening desire might be only a temporary lull and was not indicative of their loss of womenhood seemed to give great relief. Both MALINSON (1948) and HUTTON (1958), in their books written especially for the lay reader, lay emphasis on the counsel to husbands at this critical phage.

Many vomen mentioned a "dryness of the passage," causing difficulty of sexual union and a consequent less of complete satisfaction. This less of mucous secretion would appear to be a preliminary to the againg of the genital tract, detailed by McLAREN (1941), NEARS (1958) and others, resulting in marrowing of the vaginal introitus and possible formation some years later of a stenosing ring. HAMBLEN (1945) stated that the concensus of opinion was that errors of adacarine function play little part in the pathogenesis of abnormalities of libido, save in those patients in when this hypoplasia of the lower genital tract caused awaward or incomplete sexual congress. GREENBLATT (1942) however likened the role of sex hormones in libido to a "test-tubo chemical reaction" - progestorone depresses excessive libido and androgens increase deficient libido. He maintained that the "psychotic tendencies of the nymphemaniac, the neuroses and unhappiness of the frigid female and the

problems of the incompatible couple" are amonable to hormone therapy.

The fact that other women admit to an increase in libido (which can be equally distressing and frustrating) is thought by some to be due to the release from the foar of programcy. SMINCE (1954) contributes the view that, if the increase in desire is not psychological, it may be caused by an excessive secretion of advonal androgens.

Table 58 shows that of 289 women, 40% felt no loss of libido whatever, 56% stated that there was a decrease and just endor 2% stated that there was a definite increase.

| Rosiro for Intorcourso | No , 02 Womqn | Borcontago of Womon |
|---------------------------|-------------------------|------------------------|
| Unchangod. | 120 | 4.1.5% |

| Increaced | 5 | 1.7% |
| Total. | 289 | 100.0% |

TABLE 58 : LIBIDO IN 289 WOMEN

As Table 59 shows, 27 women complained of dysparounia. It was considered of interest to determine the years after the monopause that these women were interviewed, assuming that the cause of dysparounia was the less of mucous secretion, and with the passage of years it might be that this would be more evident. No significant change was noted.

TABLE 59 & DYSPAREUNIA IN 289 WOLDEN

| No. of Years 51.nco Monoyauso | No. of Wohon | No. of Womon complâtiting of Dysparounia |
|-------------------------------------|--------------|------------------------------------------------|
| 5 | 72 | 4 (5.5%) |
| 3 | 79 | 8 (10.1%) |
| 4 | 63 | 7 (11.1%) |
| 5 | 75 | 8 (10.7%) |
| Fotal marriod womon | 289 | 27 |

....

MEARS (1958) found that dysparounia as a soquel of conilo vaginitic was particularly troublocome in women who had never borne children. In the 27 women in this series complaining of dysparounia, 24 were gravida and only 3 were nullipara. Cortainly this carlier age group of menopausal women may not be regarded as being at the "senile vaginitis" stage.

Medical Advice and Treatmont of Women complaining of Change in Libide or of Dysparsunia

As was montioned earlier, the author was surprised by the number of patients in the practice who expressed relief when this subject was raised. There was on occasion an attitude of shame or bewildormont on the patient's part 1f sho had noticed an increase in 11bido, although one patient rejoiced in her "renewed youth." No patient cought medical advice for an increase in libide. Cortainly, in at least ten of the cases interviewed, the women were genuinely upset at a loss of libido. In two cases amounting to complete One woman only sought medical advice for this frigidity. frigidity and she was given a course of "Mixogen" (Organon pronaration of othinyloostradiol B.P. and mothyltostostorono B.P.) tablets under the direction of an endocrinologist. After one year, no improvement had been gained from this No medical advice was sought for dysparounia. thorapy.

SUMMARY

Of 289 women, 40% claimed that libido was unaffected by the memopause. Of the 164 women who found a decrease in "desire", only one women sought medical advice and none of the 5 women who had an increase in libido sought aid. The low incidence of "complaints" would suggest little distross on the part of the women, yot the author again stresses the relief that many women obviously felt when the subject was discussed.

As far as dysparounia was concorned, 27 women admitted to this, although none had sought advice, which suggests that its existence was not causing anxiety.

HYPERTENSION

The menopause has long been regarded as a cause of arterial hypertension and the concept of "menopausal hypertension" has gained wide acceptance. The evidence of this however seems to be based on accumulated impressions rather than on systematic study.

TAYLOR, CORCORAN and PAGE (1947) solocted 200 "menopausel" women, 179 of whom hed been castrated, the remaining 21 having "ovidence of overian failure." Their agos ranged from 20 to 59 years and a systelic blood prossure exceeding 149 mm/Hg. was found in 13% of the total group. They already knew however that 10% had shown this before the menopause and that it was not more severe after than before the menopause. Only 6 of the 200 women developed hypertension after the menopause. In the women over 40 years of age, 20% were hypertensive. a figure comparing with 23.4% for normal workers quoted in the statistics of the Heart Council of Greater They claimed therefore that hypertension is Cincinnati. no more common in menopaucal women than in the female population and condomned the use of cestrogens for se-called "monopausal hyportonsion," stating that it presumably reduced any hypertension present by relieving emotional

tonsion, possibly psychologically, and the same offect could be given by reassurance and placebes.

In an earlier paper, SCHARFER (1935) reported the treatment of 13 monopausal hypertensive patients with Theolin which affected anolieration of both the hypertension and the concomitant monopausal symptoms. He concluded that: "There is an actual lack of follicular hormone and its replacement is logically indicated."

STAIWORTH (1933), in discussing the possible acticlogy of monopausal hypertension, cnumerated some of the many theories thought to contribute - hypercholestorolasmia as a sequel of hyperplasia of the adrenal cortex, heredity, obseity, fibroids, and toxecmiss of prognancy.

ROGERS (1956) emphasized the disparity in the average degree of corenary atherescloresis between men and women of comparable age. It was postulated that an ovarian hormonal factor was responsible for the delay in the development of atherescloresis in women as compared with men. He dited the evidence of Wuest, Dry and Edwards, who in 1953 demonstrated that the degree of arteriescloresis in women subjected to bilateral copherectomy was greater than in control women but less than in control men. The

1440

provious year Pick, Stanler, Rodbard and Katz had shown that in cholosterol-fed chickens cestrogens would inhibit the development of coronary atherosclerosis and cause actual regression of established atheroscloresis. It was known that a significantly high ratio of cholestorol to phospholipids had been demonstrated in the serve of pationts with coronary atherosolorosic than in a normal control group. As ago advances, there is in normal persons a tendency for the serum cholesterol to rise and to be accompanied by a comparable rise in phospholipids. but in patients with coronary atherosolerosis the phospholipide feil to rise as rapidly, resulting in a higher ratio of cholosterol. ROGERS (1956) further citos the works of Hilert, Olivor and Boyd, who demonstrated that costrogens can produce a sharp roduction in the ratio of total cholesterol to phospholipids and these observations suggested that costrogen, with uts beneficial offect on the cholesterol phospholipid ratio, may be a factor in the lower prevalence of artorlosclorosis in women.

In 1954, NEUBERGER had summarised a paper by acknowledging that there was no unanimity of Spinion regarding the exact causes of menopausal hypertonsion.

MACGREGOR (1949) stated that the hyperpiesis found at the monopause is rarely more than 170 mm/Hg. and is typically labile. Decause it is a temporary phenomenon, he adds, it must therefore be related to endocrine imbalance.

In 449 women in this series, a blood pressure exceeding 149 mm/Hg. was found in 116 women (25.8%) and exceeding 160 mm/Hg. in 83 women (18.5%). In this last group, 7 women had no menopausal complaint whatever. Of the 83 women with a blood prossure exceeding 160 mm/Hg., 35 were from the hespital group and the remaining 48 were from the practice group.

As will be seen from Table 60, the symptome of headache, vortige and incommin were more frequent in the hypertensive group (i.e. where blood pressure exceeded 160 mm/Hg.) and as will be seen in a later chart on page 161, the relation of blood pressure to the occurrence of all symptome suggests that the hypertensive patient is more liable to have concentiant menopausal symptoms.

| | Percentage in all women | Porcentage in Women with blood prossure exceeding 160 mm/Hg. | | |
|----------|----------------------------|--------------------------------------------------------------------|--|--|
| Headache | 27.3% | 39.7% | | |
| Vortigo | 31.8% | 37.3% | | |
| Incomia | 20.4% | 34.9% | | |

TABLE 60 : INCLUENCE OF HEADACHE, VERTICO AND INSOMNIA

SUMMARY

Relating the figure of 25.6% women with a blood pressure exceeding 149 mm/Hg. to the 23.4% for normal workers cited by the Heart Council of Greater Cincinnati, no evidence of hypertension in the menopause has been shown in this series. The symptoms of headache, vertige and insemnia were found to be more evident in the hyperpietic women - which would seem to be confirmation of this triad of symptoms in the diagnosis of hypertension.

FACTORS WHICH MAY AFFECT THE SYMPTOMS OF THE MENOPAUSE

Often it is said that the symptoms of the menopause are an aggravation or claboration of a woman's temperament. It was thought wise therefore to find out whether factors occurring earlier in a woman's life might affect the frequency and occurrence of symptoms. Tables were then propared, placing the women in one of three groups:

- 1. Shope who had no symptoms at ally
- 2. those who compleined either of fluches only or of other symptoms unaccompanied by fluches;
- 3. those who had fluches and other symptoms.

| PABLE 61 8 | RELATION | OF AGE | OF 1 | UBERTY | <u>T0</u> |
|------------|------------|----------|------|--------|-----------|
| FRI | EQUENCY OF | P SYMPT(| MIS | | |

| 17-23 | 32 | 7 | 21.9% | 10 | 31.2% | 15 | 46.9% |
| Potal | 450 | 77 | | 144 | | 229 | |

As Table 61 shows, no relationship was found between the age of puberty and frequency of menopausal symptoms.

In relating the possible influence of pro-menstrual tension, it was found (see Table 62) that of the 23 weach who suffered from "severe" dyamenorrhoea, not one of these wemen was free from menopausal symptome.

TABLE 62 : RELATION OF PRE-MENSTRUAL TENSION TO FREquency of symptoms

| P. M. T. No. of Casos | No. of | No Symptoms | | Flucho | 22 2 | Flushos | |

TABLE 63 : RELATION OF DYSMENORRHOFA

TO FREQUENCY OF SIMPTOMS

The M.W.F. survey (1933) stated that, if "a normal monetruation is found to be associated with a symptomices monopauce, there may be reason to hope that in the future there will be less disturbance of health at the change of life." After the passage of three decades, however, it would seem that there is still evidence to show that premonstrual tension and dysmonorrhoes are sufficiently evident to produce an aggravation of monopausal symptoms.

The M.W.F. (1933) also found that, as far as ago at the last period was concerned, "there was little evidence that ago was an influential factor in the occurrence of symptome." Analysic of the 450 women in this survey tends to disagree. As Table 64 shows, the 139 women who were aged 51 years or over at the time of the menopause were less liable to have a symptomless menopause than the vomen who had an earlier menopause. Similarly, 54.7% of the former group exhibited "fluches + other symptoms" as compared with only 30% of the latter group.

TABLE 64 : RELATION OF MEMOPAUSAL AGE TO FREQUENCY OF SYMPTOMS

The mode of constaint of monses as Table 65 shows has no bearing on frequency of symptoms. A "sudden" constaint was where women had regular monses (although often hypomenorrhoea) prior to actual constation, and "irregular" where periods had failed to recur monthly prior to the monopause.

TABLE 65 & RELATION OF MODE OF CERSATION OF MENSES TO FREQUENCY OF SYMPTOMS

(In 448 cacos only, as 2 women failed to give accurate answers)

| Modo of No. of Cessation Cases | | No Syn | nytoms | Fluchoc or Othor Symp | | Flue Othor \$ | 0 |
|-----------------------------------|-----|--------------------|------------------|-----------------------------|---------------|--------------------|------------------|
| Cospation Cas | | No. of Cason | % Of Group | No. O2 Casos | s of Group | No. Of Casod | g og Group |

| All women | 448 | 77 | | 143 | | 558 | |

The occurrence of menopeusal symptoms prior to the actual cessation of menses has already been mentioned in relation to flushes, where it was found that flushes occurred in 36.9% of women while they were still menstructing. The remaining women developed symptoms after actual constion, but it was often difficult to ascertain the exact time when these symptoms made their appearance. Accordingly, Table 66 was propared to determine whether there was any difference in incidence of symptoms 2, 3, 4 or 5 years after the menopause.

TABLE 66 : RELATION OF NO. OF YEARS (AT TIME OF INTERVIEW) SINCE MEMOPAUSE TO FREQUENCY OF SYMPTOMS

As is shown above, the symptome of the monopause can be expected to appear within two years of the constant of monses, if in fact they did not occur before the monopause.

ł

As has been shown earlier, obesity and irritability and/or depression were found to be more marked in married women. In the M.W.F. (1933) report, the latter symptom was more marked in the unmarried. Table 67 was prepared to discover whether marital status had in fact any effect upon the overall symptometology of the monopause.

| TABLE 67 | \$ RELATION | I OP MARY | TAL STATUS |

| A11 Women | 450 | 77 | | 140 | | 229 | |

Table 67 shows that marital status has no bearing on the frequency and occurrence of the symptoms of the menopause. As far as social status was concorned, again no

statistical relationship was found, as Table 68 illustrates.

| TABLE 6 | 8 8 1 | RELATI | con op | SOCIAL | SRATUS TO |

As far as actual parity was concorned, M.W.F. (1933) found that there was a tendency for individual symptoms to be more marked amongst women who had conceived. They found however that there was no evidence to show that the proportion of symptoms increased with the number of conceptions, except in the group representing 10 or more prognancies. In this survey only full-time prognancies are compared with the occurrence of symptomatology. As Table 74 illustrates, no significant relationship was found.

| All women | 450 | 75 | | 144 | | 553 | |

Further tables were propared to relate the mode of confinement, length of married life and reproductive period to symptome. As Tables 72, 73 and 74 illustrate, no relationship was evident between these factors and symptomatology at the monopause. Initial perusal of the relation of the reproductive period to symptomatology suggested that the shorter the reproductive period, the more likely was the woman to have a symptom-free monopause, but statistical analysis on this point showed no significance.

Bocause of the interest focused on "hypertension of the menopeuse," Table 75 was propared to determine whether a relationship existed between symptomatology of the menopeuse and blood pressure. Systelic blood pressure was taken as the comparative value.

These figures show that as the systellic blood pressure increases the chance of the woman having a symptomless menopause decreases, but statistically the numbers are too small to put it beyond doubt.

In none of these tables relating factors to the incidence of symptoms was there a statistical difference in the incidence of symptomatology between the hospital and the practice groups. For this reason, the two groups were combined but full evidence is given in Tables 61A to 75A in the Appendix.

and the second second

. . . .

SUMMARY

The occurrence of dysmonorrhoes or pro-monstrual tonsion in younger hife suggests that the woman is loss liable to pass through the climactoric symptom-free; the later in life the monopause occurs, again the less likely is she to have a symptom-free "change." Linking up this latter group, it was found that the longer the reproductive period, the more likely was the woman to have symptoms, but statistical analysis of this relationship was found to be inconclusive. In the hyperpletic woman, symptoms were apparently more prominent, but statistical analysis was such that available figures were not sufficient to put the relationship boyond doubt.

WORK DISABILITY

HALDORSTEN (1954) stated that the years of the menopause are considered to be years of inferior working capacity in women. In 1951, the city of Dergen introduced a disability ponsion for persons from 15 - 69 years (after which they become eligible for an old age pension) who, on account of physical or mextal defects, were unable to In 1953, of the 2098 people drawing support themeslves. those disability pensions (1.8% of the population), 1441 (Disabled married women, with husbands wore single women. oprning a good income, did not receive the pension). Statistical survey of the population in 1953 showed a 56 surplus of women from the voting age of 21 years and, taking the figure of men as "normal," the expected mutber of ponsioned women would have been only 700. Further invostigation chowed that, when these disabled persons were grouped according to age, 82.3% of the women were in the 50 to 69 years group, as opposed to 50.2% of the man.

It is of interest to record the nature of the diseases which led to the disablement pension being granted. As Table 76 shows, norvous diseases, diseases of the bone and showsatic disease, and cardiovascular upsets were far more provalent in the women than in the men. This finding,

coupled with the age-grouping, makes the question of diseases in the post-monopausal period extremely important.

| Sonilo Dobility | 66 | 54 |
| Faboroulos1e | 106 | 89 |

The question may yet become an economic one. In America the number of women in the labour force has trobled since the beginning of the century, and the increase in the "older women" has been sixfold. HESSELFINE (1951) quotes a figure of 384,000 women per years of a given age as gainfully employed at the time of the menopause.

As far as this survey was concerned, a woman was considered disabled if one or more of the symptoms already disoussed had caused her to be absent from demostic or business duties for a period in excess of one week. The women interviewed in the hospital group had a higher incidence of "disability" than the general practice group.

| Widowed Divorced Separated | 5 | A | 8 | 9.5% | |
| Potal | 26 | 94 | 40 | | |

TABLE 77 & WORK DISABILITY (In 450 Cases)

As Table 77 shows, 40 women admitted to less of work -8.8% of the 450 women. Of the 77 single women, 12.9% were absent from work as opposed to 9.5% of the widewed, diverced or separated group and 7.3% of the married women. These results are in conflict with those of the M.W.F. curvey of 1933, in which a higher percentage of married women was "incapacitated" - 10.9% as opposed to 9.1% single vomen. The overall figure of 8.8% in this series, as compared with the average of 10.3% in the earlier survey, would suggest that treatment - or possibly a more enlightened attitude towards the menopause - has lessened the work disability over the years.

The occupations of the 450 women interviewed are of interest. Table 78 illustrates that 70 (24.2%) of the married women were in occupations outwith the home, as were 52 (61.9%) of the widewed and separated women, and 75 (97.4%) of the single women. In all therefore 43.8% of the series were gainfully employed and the working capacity of the monopausal women is consequently of the graciest importance. Reasons for incapacity are itemised in Tablec 79 - 84.

| 495 | | Ovor 1 month | Salicylates Physicthorapy |

In Cases 65, 454 and 495, the "phoumatic pains" necessitating absence from work were of recent onset, i.e. within 4-5 years. In these 3 cases a true rhoumatoid arthritic caused incapacity.

Two women (Cases 152 and 357) were unfit for work by reason of a "variety" of symptoms; in each instance, rest in bod and sedation proved bonoficial and work was resumed at the ond of the month.

This group showed the greatest loss of work in menopsusal women. Five wemen required dilatation and curottage, as did the one patient unfit for work by reason of leucerrhoes. Pyemetra was found to be present.

In 2 other womon, Cases 96 and 122, flushings were sufficiently severe to cause disability. Ostrogen therapy gave marked relief and work was resumed in each instance after one week.

SUMMARY

8.8% of women were incapacitated for a period in excess of one week by reason of symptoms generally accepted as referable to the menopause. A higher incidence of less of work was found in single women.

Excessive bleeding (bleeding persisting for more than 10 days), which was included in this thesis as a "symptom of the menopause," was responsible in 30% of cases. Of the "true" menopausal symptoms, irritability and/or depression was the most common cause of work loss and it was responsible in 18% of women.

MIDICAL ADVICE AND TREATMENT

Medical advice and treatment of individual symptoms have already been discussed, but generally it was a combination of fluchings and other symptoms that was the cause of medical advice being sought. In all, 216 (48% of total) women acked for medical aid. In only 37 of these cases was there an isolated complaint. As Table 85 shows, there was no evidence that unmarried women were more liable to sock medical advice than married women.

| na na tang tang tang tang tang tang tang | Womon Booking Modical Advice | | | |

| Widowod Divorcod Separatod | 15 | 84 | 39 | 46.4% |
| All women | 98 | 118 | 216 | 48.0% |

TABLE 85 & MEDICAL ADVICE

Of these 216 women who cought advice, all but 26 were given some therapy. The figure of 40.2% of menopausal women receiving therapy is far in excess of the 5% quoted by JEFFCOATE (1960) as in need of treatment for menopausal

symptoms. NOVAK (1952) felt that a figure of 15% of women have "vascmotor symptoms sufficiently troublesome to constitute a problem and warrant endocrine therapy."

Of the 190 women who received treatment, endoorine thorapy was given in 97 cases (21.6%); in 37 instances it was combined with sedative therapy. Sedatives only were given in 7 cases, vorbal advice in 26, and in the remaining 86 cases, treatment was aimed at rollef of individual symptoms such as rhoumatism, obseity, etc., as dotailed in carlier chapters.

THE ARTIFICIAL MENOPAUSE

ч

.

.

.

THE ARTIFICIAL MENOPAUSE

Fifty women were solocied who had had an artificial monopeuse, 32 from the practice group and the remaining 18 from the hospital patients. In the latter group, information was cought and received from the hospital where the monopeuse had been induced. In the practice group, all information was obtained from the practice files. As with the normal monopeusal women, there had been an interval of at least two but not more than five years since the cossistated the admission of the 18 women in the hospital group are lighted below.

Table 87 (see p. 178) illustraton the pathologies that necessitated the induction of the memopause in the 50 wemen selected and enumeraton the varying forms of induction.

The average age at the time of the induced menopauce was 44.7 years, the age varying from 30 years to 52 years. At the time of interview, two years had elapsed since constion of mensee in 12 wemen, three years in 15 wemen, four years in 15 wemen and five years in 8 wemen.

Twonty-five women were left with residual ovarian tissue, and the benefit of the conservation of this costrogen producing tissue is reflected in Table 88 (see p. 179) which shows that 80% of the women with no ovarian tissue were subject to both fluches and protean symptoms, as opposed to 56% of the women with surviving ovarian tissue. PABLE 88 : INDUCED MENOPAUSE IN 50 CASES

All articles read on the subject of the artificial menopause ungo the conservation of as much healthy evarian tissue as possible and Table 89 was prepared to contrast the incidence of symptoms in the normal and in the induced menopause, further sub-dividing the artificial menopausal group into Group T where there was residual ovarian tissue, and Group II where there was none.

In no instance, in Groups I and II, was there a complete absence of symptoms. Further, the incidence of flushing, headache, irritability and/or depression, vortige, undue fatigue, rhoumatic paine, incommia, backache, pruritis, leucorrhoes, pains in the breasts, excessive bleeding and dyspareunia were all substantially greater than in the normal monopause. The only symptom found to be more frequent in the normal monopause was obesity. In contracting the Groups I and II, all symptoms but headache, obosity, pruritie, changes in the skin and hair and excessive bleeding were more commonly encountered in Group II where there was no residual ovarian tissue. Group I - Residual ovarian tissue Group II -No ovarian tissue Since so much emphasis has been laid on flushes as the only "true" symptom of the menopause, Table 90 was propared to contrast the degree of flushes after the artificial senopause, with reference to mode of cessition of menses.

Soven women (14%) had experienced no flushing whatever at the time of interview, and in six of these women overien tissue had been conserved. Flushing was found to be more common and of a more severe type in women with no residual ovarian tissue.

Eight women (16%) experienced fluching before operation, as opposed to the 36.9% of women who experienced fluching before a natural menopause. DONALDSON and NASSIM (1954) found fluching present in 75% of their artificial menopausal eases and, unlike this series, found no significant difference in patients who had a surgical menopause and these with a radius menopause. As Table 90 (see p. 182) illustrates, the ten women in this series subjected to either radius or deep therapy suffered from mederate or severe fluching.

MoLAREN (1941) in his series found the incidence of moderate or severe fluching three times greater when the menopause was induced by rediction or castration than when the menopause occurred spontaneously. In this study, 38.4% of normal menopausal women had moderate or severe fluching

.

,

compared to 68% with no ovarian tissue and 52% where ovarian tissue had been conserved.

RICHARDS (1951) found the incidence of fluching to be doubled in women who had hysterectomy with unilateral copheroctomy, as opposed to women with hysterectomy only, and trobled in women where both ovaries had been removed. In this series, the comparable figures would disagree, being 80% in hysterectomy only, 73% where one ovary was conserved and 100% in bilateral copherectomy.

A furthor point made by DONALDSON and NASSIM (1954) was that evidence of fluching was higher in the younger age group. As Table 91 shows, this was substantiated in this cories.

LIBIDO AFTER INDUCED MENOPAUSE

Change in libido following an artificial menopause has long been studied. DONALDSON and MASSIM (1954) quote Battey writing in 1876: "The aphrodician propensity was not annulled after the removal of the ovaries." In a comprohensive paper on the "ill effects of the radium menopause," MeLANEN (1950) found that of the 50% of the vomen who had "any interest in cor" before radium, 50% of the remainder generally became sexually anaesthetic after therapy. DONALDSON and MASSIM (1954) analysing the findinge of several investigations into the induced menopeuse, found a varying percentage of patients had decreased libido, but did find the percentage higher in younger age groups.

Of 32 women in this series of 50 patients, 15 women admitted to a decrease in sexual feeling, 14 women stated that there was no change, and 3 women had noticed an increased desire.

As Table 92 shows, there was a slightly greater incidence of decreased libide in the younger women, although in the 450 women passing through the normal menopause, a greater incidence of 56.8% of women were found to have decreased sexual feelings.

184,

| 45* | 81 | 11(52.4%) | 9(42.8%) | 1 (4.8%) | | | |
| Total | nan se | 14(43.7%) | 15(46.9%) | 3 (9.4%) | | | |

Table 93 was prepared to contrast libido in Groups I

and II.

TABLE 93 : COMPARING LIBIDO IN WOMEN WITH OVARIAN TISSUE AND THOSE WITH NO RESIDUAL OVARIAN TISSUE IN 32 WOMEN

| Monopense | iro. or | Lebier | | | | | |
|----------------------------------------------|----------|-----------|-----------|-------------|--|--|--|
| Induced by: | Patiente | imohanged | Decreased | Increased | | | |
| Hystorectony only | | 4 | 8 | 1 | | | |
| Hysteractony and removal of one. ovary | 8 | 3 | 5 | ن ته | | | |
| <i>Rotal</i> | 15 | 7(46.7%) | 7(46.7%) | 1 (6.6%) | | | |
| Panhystorectomy | 8 | 2 | 5 | 1 : | | | |
| Redium | 6 | 3 | 3 | | | | |
| Doop Therapy | 1 | 1 | 6110 | cité | | | |
| Bilatoral Oophoroatomy | \$ | 1 | 623)a | 6323 | | | |
| Total | 17 | 7(41.2%) | 8(47.1%) | 2(11.7%) | | | |

From those figures there is no apparent difference in libide between women with and these without ovarian tissue. NICHANDS (1951) had found a greater incidence of less of libide in women with bilateral copherectomy and hystorectomy (60%) as opposed to 42% in women with hystorectomy and unilateral copherectomy and 35% in women with hystorectomy only.

Many writers, including MoLAREN (1950), condomn the radium monopause because of the severity of ensuing monopausal symptoms and the sexual ancesthesia. Unfortunately, no control series of patients was found to compare the question of libido in earlier studies. As has been already mentioned, the decrease of "sex urge" was found to be no more marked in the normal monopausal woman in this series. then in the woman subjected to a surgical menopause. Leaving the field open, McLANEN (1950) felt that, when this control series could be found, it was possible that no great difference would be disclosed, though his condemnation still persisted because of the <u>premeture</u> lease of the sex urge.

Though the numbers involved cannot bear statistical comparison, it is surprising to note that 3 of the 32 women had noticed a definite increase in libide - 9.4% as opposed to 1.7% of women who had a spontaneous memopause. Could this be because a younger ago group was involved? Since 2

of the women were in the -45 age group, this is a possible explanation. Or could it be psychological?

MEDICAL ADVICE AND THE ARTIFICIAL MENOPAUSE

Of the 50 wemen, medical advice was sought by 38 wemen because of memorrhagia, and surgical intervention ensued. Thereafter, 32 wemen (64%) required medical and for treatment of memopausal symptoms - 16 of when had residual ovarian tissue. As will be seen in Table 94, these 16 wemen had a less severe symptomatology and in 9 wemen one symptom only necessitated medical advice, as opposed to 5 wemen with no residual ovarian tissue who sought advice because of a single symptom.

Treatment was directed at the presenting symptoms, as with the group of women with a normal menopause.

TADLE 94

r

INCAPACITY IN THE APTIFICIAL MENOPAUSE

Twenty-one women were incepecitated by menorrhagin, and subsequent to "operative treatment," 5 women (10%) were absent from work or domestic dutice, 2 of when had residual ovarian tissue. In 3 instances, irritability and depression were the offendors, one women receiving shock therapy on hospitalization and the other two sedation. The two women incepacitated by rhoumatic pains were both given physiotherapy, one with cortisone injections and the other with gold therapy.

SUMMARX

Fifty wemen were selected who had had an artificial menopeuse as opposed to the random sample of 450 wemen who had had a natural conduction of mensos. The average age of the 50 wemen at the time of surgical menopeuse was 44.7 years. Varying pathologies had necessitated intervention and 25 wemen had residual overlan tissue after the operation.

No woman was found to have had a symptom-free climactoric and there was evidence that symptoms in all 50 women were greater than in the cases with a natural menopause. Indeed, in the 25 women with no residual ovarian tissue, symptoms wore even more ovident.

There was further ovidence to show that a woman subjected to radium or deep therapy was liable to have "moderate" or "sovere" fluching as opposed to mild fluching or none at all.

The younger the patient at the time of the surgical menopause, the more liable she was to be subject to fluching.

There was no proof of libido being affected advorsely by surgical induction.

64% of women sought medical aid after the surgical memopause and in the women with no residual ovarian tissue, 11 of the 16 women complained of several symptoms as opposed to 7 of the 16 women with residual ovarian tissue.

10% of women were incapacitated and absent from work or from household duties subsequent to surgical intervention.

<u>COMMENT</u>

.

It is apparent from discussion in provious pages that the climateric is a condition with many facets, only one of which is controgon depletion. It cannot and must not be regarded as a disease, but rather as a summation of several independent factors.

It soems important to omphasice once more that the occurrence of the menopause (actual constition of menses) is an incident in the ora of the climactoric which is initiated by the againg process of the every, with a subsequent disruption of the previously reciprocal interaction of the pituitary and everies. To say this is a simple explanation of the cause of the symptoms of the climactoric would be glaringly incorrect. Much has yet to be learned of the hormonal interplay which may be a constant factor in inconstant women.

Interestingly enough, the human female is the only monstructing primete who ceases monstructing during her life span, and in this series the average age of monopause was found to be 48.7 years. The figure of 48.7 years is closely allied to Bachman's (1947) findings. The fact that he found the memopause to be retarded by three years in the last century was based on a statistical survey. He mentioned the possible cause as factors in a voman's life or social change. As far as this thesis was concerned, no cause in a woman's pro-memopausal life was found statistically to influence the age of cospation of memors.

What was of interest was the increasing number of women having a monopauso after the age of 50 years in the last 20 As has been mentioned earlier, costrogen therapy yoers. could be blamed for this deforment of monopause, but the author again insists that none of the practice patients received hormone therapy until one year after concation of monses (and any blocking thereafter was considered to be Porusel of Table 2A in the Appendix shows nathological). that in the practice group 75 women were in the 504 age group, and in the hospital group 64 women were in the same The author cannot presume that this latter oategory. group had not recolved cestrogen when menses persisted, so analysis of the practice group only was tackled. An ovon larger number (33.3%) of women are then placed in the 50+ ago group.

A fashionable view of social conditions affecting menopausal ago was provalent in the last contury, when it was considered unfair to compare the "operatives in a large industrial city" with "ladies of higher classes" because of contracting cocial conditions and genoral health. Indoed. writers in the 19th contury directed a great deal of study to factors such as netionality (the more civilised races wore reputed to have a later menopause), physical health (the poor woman, both physically and socially, reputedly having an carlior monopause), physical build (the fat women wore said to have an earlier monopause), colouring of hair (where the brunctto had a later cessation of meases than her blonde sister) and herodity. Since no factor was found to influonce menopeyeel ago in this thesis, one can only accore that social revolution has in fact delayed menopeuse in this ora.

Prior to the actual menopause the alterations in ovarian function may be reflected in disturbances of uterine bleeding, and there are a number of patterns in which uterine bleeding may change; the simplest of these was gradually diminishing monses without disturbance of monstrual pattern as found in 21% of women.

Fluching, which was present in 73.7% of women, had been experienced by 36.9% of these women prior to the constion Being the commonest symptom of the elimactoric of monsoe. and regarded by some as the only true symptom of this era, it demands attention of both patient and physician. Sinco wellnigh one third of the women who experience fluchings adalt to their occurrence prior to the menopause, it seems reasonable to accept that an costrogen depletion phase has started and a hormonal factor is responsible for their Yot, as Tablo 26 shows, the "nervous" women occurronco. is more liable to have severe fluching, and the statement that the climactoric is an aggravation of a patient's personality cannot be wholly ignored. This view is onhonced by the finding that a woman prons to promonstrual tonsion is more liable to suffer from symptoms of the climactoric. Indeed, if her premenstruel tension is severe, she is unlikely to pass through the climactoric symptom-free.

Tet, statistics of the incidence of cardiovescular upsets, rhoumatic disease and nervous disease show that they are more provalent in middle aged women than in mon (<u>vide</u> Table 76). Is it then justifiable to distinguish the symptoms of the elimactoric from post-menopausal elimical

problems accoriated with atrophic changes in the tissues, or do we assume that a state of hypo-ovarianism can be an initiating factor in these changes? The answer would soom simply to be that a process of againg has been started in the body and the timing is such that the olimactoric is assumed responsible. Unfortunately, too often the elimactoric is assumed to be the cause of many cohos and pains. and a very different or sinister pathology may be ignored. This the author feels most strongly and hopes that it has been shown in preceding pages. Too often is heards 19Th is the change" or some other off-putting remark, when further investigation or caroful examination would give a totally different enswor.

That the menopause may have a depressing effect on the true woman and mother must be admowledged almost as much as storilisation may depress a younger mother. An appreciation of woman's personality must be linked with an appreciation of the elimactoric, and few woman can ignore conturies of folklore or the cortainty of middle age. True involutional melanchelia was not encountered in this series, but 41.3% of the woman admitted to either nervousness or izritability, and its occurrence was more likely in women who had experienced premenstrual tonsion. Novertheless, in the 339 women who had never had premenstrual tension, there was an incidence of 38.6% of "norvous or irritable" women. The number of women who actually sought medical aid was 39 (8.7% of all women).

A middle aged woman complaining of lassitude, "feeling fed up," or apprehensive is a common enough finding, and the incidence of 8.7% would seem a representative figure to a practitioner. Unfortunately, too often she is regarded as a neurotic, and her "age" is a convenient excuse for lack of sympathy or treatment. Surely this high incidence domands some careful consideration, and whether the cause is hormonal or due to extraneous upsets may be difficult to assess. The author's view is that undoubtedly the elimactoric provides fortile soil for nervous upset and should be regarded basically as a true symptom of the era, though not necessarily one to be treated with hormones.

With regard to vertigo, of the 145 women found to have this complaint, 18 wemen sought medical aid, and in 50% of these women other causes of vertige were evident. In the 29 women who sought advice for headable, 48% had hypertension. With the symptom of backache, 63.6% of the women had a concomitant complaint such as obesity, rhoumatic paims,

loucorrhoes or vaginal blooding that could have been responsible for the backsohe. Again in insemmia, treatment was generally given for a pathology directly responsible for the incommia, such as fluching or hypertension. Similarly with pruvitus, 50% of the venen requesting medical help vere treated for a general illness.

To summarise - the symptoms of vertige, headache, backache, insomnia and pruritus vulvee should not necessarily be regarded as a sequel of cestrogen deficiency.

What 1s obesity? The higher incidence of this eventor occurring in married women does echo Langdon-Brown's sentiment that it is less easy for the spinster to coddle Can there be an endocrine basis for the "middle horsolf. aged ppread?" Cortainly, in the 19 women who cought medical ald (18 of whom wore married), a somewhat unscientific link with a sub-thyrold state (showing in "changes in skin and hair) was present in 5 women. (26.3% as opposed to 8.7% in the whole cories). The obese patient, "sticking" to a dist with no weight long, can be Trustrating for both patient and doctor alike but until (if at all) a more evident endeerine basis is ostablished, dictary regime must remain the rather harsh basis of therapy.

The author reminds the reader that "rhoumatic pains" was presumed present whether the patient had a fibrogitie. myalgle. or some other minor form of "muscular rhounetism". or "joint pains" or a true rhoumatoid arthritis. It ie consequently difficult to assess this symptom, when a true definition of "menopausal arthralgia" has never been made. Nevertheless, it is known that joint pains are more common in middle aged women than in mon, and a cauge for this marked difference in the sexes has never been elicited. In 51% of women seeking advice, no contributing cause for the occurrence of rheumatic pains could be found. Can this then be included in the group with a hormonal basis? Because of the indefinite interpretation of "menopausal. arthralate" and coloction of sufferers, it would be presumptions of the author to comment.

Procuming that the physiological changes in the vagina do not cause a discharge, it is possibly erroneous to include leucorrhoes as a symptom <u>per so</u> of the elimactoric. Its cocurrence as far as the author is concerned is more apparent in the adelescent and young woman than in the woman in hor fifties. Despite its low incidence, the complaint of pains in breasts would seem a possible true symptom of the climactoric. Since all wemen admitting to this symptom had accompanying fluches, it seems reasonable to assume that hormonal imbalance is the responsible factor.

Since no true hypo-thyroidiem was found in any of the women complaining of changes in the skin or hair, and since there is so much conflict in the literature of the actual existence of a sub-clinical thyroid state at the climactoric, it would be wrong to comment further, other than to say that no evidence was found to confirm upset of thyroid function in this series.

Of particular interest were the findings related to blood pressure in women. That there is a true "memopausal hypertension" is not accepted, although experimental work would suggest that there is a link between controgens and arteriosclorosis. As Table 75 has shown, the hypertensive patient is less liable to pass through the elimactoric symptom-free, but as Table 26 shows, variation in blood pressure does not influence the incidence of flushing. If it is accepted that flushes are the only true symptom of this era, then this finding suggests that the other symptoms discussed in this paper are in fact expressions of an agoing process coincidental to hormonal imbalance.

What of factors that may influence this symptometology other than blood pressure? It has already been mentioned that premenstrual tension plays a rôle in the evidence of symptoms, and the woman prone to dysmemorrhoes would also seen lieble to have complaints at the climactoric. Apart from those menstrual disorders, the only other factor found to have an influence on symptometology was the age at meno-Here it was found that the younger the woman was DEUSO . at the time of cesetion of menses, the more likely she was to have a symptom-free menopause. A oriticism here could be that the younger woman interviewed in her forties could yet be prone to avaptome at a much later ago. A not uncommon finding in practice is to visit a patient in her cirties or even seventies still exhibiting flushes. Table 66 would suggest that most symptoms do make an appearance within two years of cossetion of monses, but with the accepted gradual againg of the overy and hormonal secretion losconing, one cannot dogmatice as to exact timing of costrogen depletion sufficient to trigger the cause of fluching. Because of this point of practical observation. the author is disinclined to argue from the statistics provided that the older monopausal patient is more prone to

symptoms, or is it that the agoing process, here again, has not "caught up" with her younger sister.

Now is the time to remind the reader that 17% of women wore found to pass through the olimactoric with none of the symptoms generally attributable to the climactoric. Not so fortunate were the 50 women in this series who had an artificial monopause. Not one of these women was free from Indeed, all symptoms appeared aggravated in the exmptome. artificial monopauso. The need for modical advice would appear a conclble yardstick by which to measure severity of symptoms, and in the group of women with an artificial menopeuse 64% of the women sought medical aid as opposed to 48% of the women who had undergene a normal menopeuse. Further 6.2% of women in the latter group were "disablod" or unfit for work as a consequence of symptoms (other then memorrhagia), and the comparable figure in those who had undergone an artificial monopause was 10%. This contrast in flaurds should certainly quieten those who maintain that the artificial menopause is no more upsetting to a woman than the normal menopeuse.

505°

Treatment of woman "in the monopause" receives much attention from physicians, and the author admits that her views on this aspect of the elimactoric have changed since this paper was started. Not to "meddle with the monses" must be the prime consideration in treatment, and any prememopausal symptoms must be dealt with without hermonal therapy. Accuming that monopause has been present for more than one year, the decision to use hermones must then be an individual one, and the figure of 21% who received costrogens in this series would be far in excess of what some physicians would consider essential.

A recent publication from the Office of Health Economics entitled "The Costs of Medical Care" allocates the expenditure of £1,000,000,000+ by the Mational Health Service in 1961 in England and Wales. Included in this statistical analysis are the costs of the general medical corvices and the cost of prescriptions. The pattern of expenditure is said to indicate the relative prevalence of different diagnoses in general practice (except these connected with pregnancy). Under the heading of "Monopausal Symptoms" £400,000 has been allocated to general medical services and £400,000 to the pharmaceutical services. This is exclusive of hespitals. To what this figure alludes is difficult to accertain, as other "diagnostic groups" such as mental disorders, vascular lesions, diseases of skin, bones and movement organs, headache, backache, vertige, obsity, incompia, etc. appear to cover symptoms discussed earlier in The author wrote to the Office of Health this paper. Beominics asking if flushes only were assumed to be "menopausal symptoms" as other symptoms seemed evident in The Director, Dr. M. F. 100. othor diagnostic groups. supplied the information that the "menopeusal symptoms" accounted for 0.56% of the total diagnosis and the inclusion of a symptom in this group - "covoring the bread range of symptoms presented at the menopeuse, and not only the flushings" - depended entirely on the judgment of the dector making the Could this be enother example of "asylum diagnosis. lanorentileo?"

What has this thesis accomplished? The author has often heard doctors, in a rather derogatory fashion, dismissing ailments of a middle aged woman as due to "the change," "her age" or more unkindly "neurosic." The figures quoted from "The Costs of Medical Care" would suggest that a woman is conveniently regarded as "menopausal" when no other diagnosis can be found. It would seen that this illunderstood process of the climactoric has no place in this scientific age of medicine. And yet, as has been shown in this thesis, a superficial examination in many women can reveal a pathological basis related to ageing of tissues, causing a symptom generally regarded as "menopausal." What if no physical cause can be found? Is she then a neurotic, a nuisance or a moody individual? Until the hormonal imbalance present at the time of the climacteric is fully understood, the "impressive monument of suffering" surely merits consideration of extraneous factors such as environment and personality, and sympathetic counsel.

ACKNOWLEDGEMINTS

.

I am ploaned to acknowledge the work of the Steering Committee of the Medical Women's Federation in the preparation of the format of the questionnaire, coupled with the help, both financial and friendly, of the Muirhead Trust. I am particularly indebted to Dr. Alwyn Smith for his interest and pertinent curvey of the paper.

To my partner, Dr. Keto Herrowor, O.B.E., I am again indebtody her encouragement never wavered, despite the slow progress of this work.

I also one gratitude to my brother, Dr. J. F. Ademo, M.D. (Hons.), for persistent criticism, bitterly resonted at all times, but an effective opur to further writing.

Professor Ian Donald kindly advised in the proparation of this thesis and Dr. Agnes Stowart willingly commented on its final draft.

My thanks go also to the librarians of the Glasgov University Library, The British Modical Association Library and the Medical Department of the British Drug Houses Ltd.

Mrs. Mary Saith, the practice secretary, kindly helped with the typing of some of the original drafts and Miss Irone Breen was responsible for the final typing of the thesis. Finally, to the patients themselves I offer appreciation of their op-operation and help.

In relating factors which may influence the symptoms of the menopause in the two groups, namely the hospital and the practice groups, only the percentage incidence (and not the actual number of women) in each category is given. In this way, the tables are more concise and equally intelligible.

TABLE 61A : RELATION OF AGE AT PUBLERTY TO FREQUENCY OF SYMPTOMS IN THE NOSPITAL AND PRACTICE GROUPS
